It is, therefore, suggested that normal bile contains an enzyme which promotes the absorption of fat by dehydrogenating it, and that the enzyme is absent after pancreatectomy.

PETERSON, R. E. and ETINGER, R. H. **Radio-active iron absorption in siderosis (hemochromatosis) of the liver.** *Amer. J. Med.*, 1953, **15**, 518-524. [Dept. Biochem., Army Med. Serv. Grad. Sch., Walter Reed Army Med. Centre, Washington, D.C.]

Physiological amounts of ferric ^{59}Fe were given by mouth to 4 normal subjects and 2 patients with siderosis. In the normal subjects only from 1 to 4 per cent. of the Fe was absorbed, and the amount absorbed was almost identical with that detected in the red blood cells. Radio-active Fe was undetectable in the serum at 2 hr., the period of highest concentration in whole blood. In siderosis from 20 to 45 per cent. of the Fe given was absorbed. In one patient from whom stored Fe had been removed by repeated bleeding the amount of ^{59}Fe absorbed and the amount present in the red blood cells were identical, but increased absorption was indicated by the high serum Fe level at 2 hr., as well as by the balance technique. In a patient with hepatic siderosis the amount of ^{59}Fe absorbed was nearly 3 times as great as the amount found in the red blood cells. The use of red blood cell uptake of Fe as the sole index of absorption is therefore not reliable in patients with increased Fe storage. The very high rate of absorption in this patient was demonstrated also by a high ^{59}Fe level in the serum at 2 hr. It is suggested that after removal of stored Fe patients with haemochromatosis should be maintained in a state of slight hypochromic anaemia by frequent bleeding and phosphate administration.

SINGER, H., SPORN, J. and NECHELES, H. **Mann-Williamson ulcer: analysis of digestion and absorption.** *Amer. J. Physiol.*, 1953, **175**, 322-326. [Dept. Gastrointestinal Res., Med. Res. Inst., Michael Reese Hosp., Chicago, Ill.]

In one group the dogs were prepared by a typical Mann Williamson operation, and in the other by a modification of it in which the pyloric antrum and the duodenal loop opened proximally by a cannula and distally into the terminal ileum. The Mann Williamson dogs survived between 18

and 96 days and showed delayed and decreased digestion and absorption of gelatine, but all 3 dogs in the second group had unimpaired digestion and absorption of gelatine and were still in good health after 200 days. Absorption of glycine and sugar was normal in both groups. Absorption of particulate fat occurred in 7 out of 12 Mann Williamson dogs, despite the absence of bile.

The reduced absorbing surface and the altered protein digestion are thought to be significant in the production of Mann Williamson ulcers.

SIMONNET, H. and LE BARS, H. Relations entre la motricité du rumen et la glycémie chez le mouton. [Relation between rumen motility and blood sugar in the sheep.] *C.R. Acad. Sci.*, 1953, **237**, 751-753.

High or low blood sugar was induced in sheep by injection of glucose or insulin. Glucose at the rate of 2 g. per kg. bodyweight produced high blood sugar followed by a fall to below normal. The frequency and strength of rumen contractions were reduced when blood sugar was high, but the strength of contractions returned to normal during the phase of low blood sugar. This was followed by rumination characterised in the usual way by increase in both strength and frequency of contraction. The low blood sugar after insulin was accompanied by increased frequency and strength of contraction and rumination. It is considered that the movements of the rumen and other parts of the stomach are influenced by

PFANDER, W. H. and PHILLIPSON, A. T. **The rates of absorption of acetic, propionic and *n*-butyric acids.** *J. Physiol.*, 1953, **122**, 102–110. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Sheep previously provided with rumen cannulae were starved for 18 hr., then the rumen was emptied and washed out. The sheep were anaesthetised and the rumen was isolated from the rest of the

digestive tract. Solutions containing acetic, propionic and butyric acids in Krebs bicarbonate saline were introduced and their concentrations were kept constant by introduction of more acids from a burette, which served as an index to the rate of absorption.

At pH 5.6 to 6.5 the rates of absorption, in descending order, were acetic, butyric and propionic. In 2 unanaesthetised feeding sheep the order was thought to be the same, but the rate of disappearance was slower. Metabolism of butyric acid is considered to be an important source of energy.—D. Duncan.

ROCHE, J., DERRIEN, Y. and ROQUES, M. Sur le remplacement des hémoglobines de type adulte par celles de type foetal au cours du développement embryonnaire et après la naissance, chez l'homme et chez le boeuf. [Replacement of adult type haemoglobin by foetal type during embryonic development and after birth in man and cattle.] *Bull. Soc. Chim. biol.*, 1953, **35**, 933–943. [Lab. Biochim. Gén., Coll. de France.]

[The title is as shown above.]

The haemoglobins were prepared by the method of Drabkin (*J. Biol. Chem.*, 1946, **164**, 703). A series of curves illustrates the variations in solubility of total carboxyhaemoglobin as a function of the concentration in equimolar solution of mono- and di-potassium phosphates.

Two types of adult and 3 of foetal Hb are distinguished in man, and 3 and 4 types, respectively, in cattle. In adult men and cattle there was always a small proportion of alkali-resistant, or "foetal", Hb. The percentage of the foetal fraction in Hb from human foetuses was 95 at 4 to 5 months, and about 80 during the last 3 months of gestation. It fell to 70 at about 2 months after birth, to 23 at 3 months, and reached the adult level of 3 to 7 at between 6 and 12 months. The time required for the transition from the mixture present at birth to the adult mixture was not greatly different from the average life of a red cell, *i.e.*, 120 days. The change is considered to be associated with the state of development of blood-forming organs rather than with conditions of oxygenation. The plateau observed in man during the last 3 months of gestation and the first month of life, with about 80 per cent. foetal Hb, is replaced in cattle by a steady increase, but the adult level is reached in both species at about the same time.—D. Duncan.

1922

DRESCHER, H. and KÜNZER, W. Die Hämoglobintypen des Neugeborenen. [The types of haemoglobin in the newborn infant.] *Arch. Gynäkol.*, 1953, **182**, 698–706. [Frauenklin., Univ. Würzburg.]

Denaturing experiments with alkali led to the conclusion that only 2 types of Hb, foetal and adult, are present in the blood of newborn infants. In 23 full-term infants, foetal Hb amounted on the average to 74.1 per cent. of the total Hb in cord blood and fell to 70.9 per cent. in capillary blood at 12 hr. after birth, and to 64.0 per cent. after 6 days. In 8 premature infants the proportion of foetal Hb fell from 80.7 per cent. in cord blood to 73.8 per cent. in capillary blood after 8 days.

BANERJEE, B. Haematological standards of students and nurses of the Assam Medical College, Dibrugarh. *Indian J. Physiol. Allied Sci.*, 1953, **7**, 175–181. [Dept. Physiol., Assam Med. Coll., Dibrugarh.]

The data were obtained from 73 men and 12 women students and 38 nurses. The mean values and standard deviations for these groups were: red cell count 5.2 ± 0.9 , 4.2 ± 0.48 and 4.08 ± 0.48 millions per c.mm.; Hb 14.76 ± 1.12 , 12.65 ± 0.78 and 12.1 ± 1.5 g. per 100 ml.; cell volume 44.2 ± 4.4 , 39.5 ± 2.2 and 39.1 ± 4.0 per cent. The data for mean cell volume and Hb content and for sedimentation rates also are tabulated. (See Abst. 4922, Vol. 23).—D. Harvey.

1924

ELLIS, B. C. Plasma and total blood volume estimations by the T1824-haematocrit method. The normal values on the Witwatersrand-altitude 5,740 feet. *S. African J. Med. Sci.*, 1953, **18**, 45–56. [Dept. Clin. Pathol., Univ. Witwatersrand, Johannesburg.]

Techniques and results are given for measurements made on 20 healthy South African white males between 20 and 48 years of age. Ranges and mean values for the data, with standard deviations for the blood, are: height, 160 to 185, 176 cm.; weight 61.4 to 86.9, 71.5 kg.; plasma volume, 2240 to 3360, 2800 ± 265.3 ml.; total blood volume, 4180 to 6270, 5370 ± 588.0 ml.; red cell volume 1940 to 3150, 2570 ± 360.8 ml.; venous packed cell volume 44.1 to 52.9, 49.7 ± 2.25 per cent. Comparison is made with data from 6 sources at sea level and 2 at 800 ft. on the basis of volumes per unit bodyweight; the Johannesburg values show reductions of 13 and 8 per cent., respectively, for plasma and total volume and no significant difference for red cell volume.

The evidence for the existence of mild polycythaemia is briefly reviewed and it is suggested that 2 mechanisms may exist, by the first of which adaptation to reduced barometric pressure is brought about by a decrease in plasma volume. At higher altitudes the second, an increase in the volume of circulating red cells, begins to operate.

CASSELLS, D. E. and MORSE, M. **Arterial blood gases and acid-base balance in normal children.** *J. Clin. Invest.*, 1953, **32**, 824-836. [Dept. Paediat., Clin. Univ. Chicago, Ill.]

This study, of 41 children up to 10 years of age and of 63 boys between 11 and 17 years old, was undertaken to define the range of values in healthy children.

Hb value increased with age from 12.3 g. per 100 ml. at 2 years to 14.7 g. at 15 to 17 years. Mean percentage arterial oxygen saturation was 94.2 at 2 to 4 years, but had reached the adult level of 95.8 in children of 7 to 17 years. The CO_2 content of arterial blood increased with age from a mean of 40.1 vol. per cent. at 2 to 3 years to 44.4 vol. at 4 to 6 years and 48.5 vol. in the adult. The alkali reserve increased similarly. Arterial CO_2 tension rose at 13 years from 38 mm. Hg to the adult level of 41 mm. The acid-base balance showed some excess acid and CO_2 deficit in children below 12 years. The electrolyte balance showed a gradual rise in serum bicarbonate in adolescence, but no compensating change in other ions was detected.—M. S. Fraser.

1929

LINHARD, J., BUSSON, F., TRAPET, P., GIRAUD, P., LECOCQ, F. and GUYONNET, C. Variation de la protéinémie sérique relative chez l'Africain de Dakar au cours de l'année. [Variations in the serum protein concentration of Africans in Dakar in the course of the year.] *Méd. trop.*, 1953, **13**, 530-533. [Org. Enquête Étude Anthropol. Pop. Indigènes A.O.F. Aliment, Nutrit.]

Total serum protein was estimated monthly throughout the year in a large series of Africans and a small series of Europeans, all resident in Dakar. The mean values for Europeans were consistently lower than those for Africans, but in both the values showed a seasonal variation. At the beginning of the hot weather there was a sudden fall followed by a steady rise to a value which was above the initial and persisted during the remainder of the hot weather; a short rise occurred at the start of the cold weather, followed by a fall to the initial value.—L. Wills.

WADSWORTH, G. R. and OLIVEIRO, C. J. **Plasma protein concentration of normal adults living in Singapore.** *Brit. Med. J.*, 1953, ii, 1138-1139. [Dept. Physiol., Univ. Malaya, Singapore.]

Plasma protein concentration was estimated by the copper sulphate specific gravity method and the accuracy of the method was tested against estimations of total N by the macro-Kjeldahl method.

Mean values for 80 men and 59 women were 7.8 g. and 7.6 g. per 100 ml., respectively. Differences between mean values for Asians and Europeans were not statistically significant.—F. C. Aitken.

1931

CLOSE, J. Étude électrophorétique des protéines sériques de cas de kwashiorkor. [**Electrophoretic study of the serum proteins in cases of kwashiorkor.**] *Ann. Soc. belg. Méd. trop.*, 1953, **33**, 185-202. [I.R.S.A.C., Centre du Kivu, Liwiro, Belgian Congo.] Flemish summary.

An electrophoretic study of serum proteins was made in 15 African infants with untreated kwashiorkor; the figures obtained were compared with those from normal African infants of the same age. The respective mean values in g. per 100 ml. were: albumin 1.1 and 3.07, α -globulin 1.1 and 0.48, β -globulin 0.4 and 0.13, γ -globulin 1.5 and 1.85. A curve from a single adult with the disease showed similar changes. The presence also of abnormal proteins was suggested by the shape of the curves. The changes in serum proteins were followed during treatment with a diet of enriched milk. There was an immediate rise in serum albumin, which had often returned to normal after 3 weeks' treatment, and at the same time there was a moderate increase in γ -globulin. The α - and β -globulins showed variable changes. One patient developed typhoid 5 weeks after the beginning of treatment; there was an immediate fall in the total protein due to a fall in both albumin and γ -globulin, followed as convalescence began by a rise in γ -globulin, though albumin continued to fall.—L. Wills.

1932

VITELLI, A., GRANDIS, C. and VITELLI PACCES, L. L'assorbimento del siero nell'ultravioletto per lo studio della composizione proteica e del contenuto in aminoacidi aromatici. 1. La curva di assorbimento dei sieri di soggetti normali. [**Absorption of ultraviolet light by serum for the study of its protein composition and content of aromatic amino-acids. 1. The absorption curve of serum from normal subjects.**] *Arch. Sci. biol., Bologna*, 1953, **37**, 332-339. [Clin. Med., Univ. Turin.]

Vol. 24, No. 2

The ultraviolet absorption curves at pH 10 and pH 2 of sera from 14 healthy subjects aged from 25 to 35 years showed notable constancy in behaviour in both alkaline and acid solution. That this absorption depends entirely on the aromatic amino-acid content of the serum protein fractions has been confirmed by parallel estimation with tyrosine, tryptophan and phenylalanine. In NaOH the curve of the mixture of the 3 amino-acids is completely superposable on the theoretical curve obtained from the sum of the 3 separate absorptions and is the same as the curve of normal sera. In acid solution there are slight deviations from these results. The constancy of the absorption curves for normal sera will allow useful comparisons to be made with pathological sera and proteins of other organic fluids and may make it possible to estimate the 3 amino-acids responsible.—M. B. Richards.

BLASS, J., ROUHI, A., LECOMTE, O. and MACHE-BOEUF, M. Recherches sur les constituants azotés des extraits lipidiques du sang (amino-acides, peptides, éthanolamine). [**The nitrogenous constituents of lipid extracts of blood (amino-acids, peptides, ethanolamine).**] *Bull. Soc. Chim. biol.*, 1953, **35**, 959-968. [Serv. Chim. Biol., Inst. Pasteur, Paris.]

The light petroleum extracts of human and horse plasma and red cells contain nitrogenous impurities and amino-acids as well as lipids. The amino-acids can be removed by dialysis or electro-dialysis, but this does not remove all nitrogenous matter, as is shown by chromatography. The purified lipids on hydrolysis liberate amino-acids which were bound probably as lipopeptides. Ethanolamine was found in small amounts in the lipids of blood plasma. The amino-acids found were in agreement with the findings of Wynn and Williams (Abst. 2029, Vol. 20).—W. Godden.

GITLIN, D. and JANEWAY, C. A. The dynamic equilibrium between circulating and extra-vascular plasma proteins. *Science*, 1953, **118**, 301–302. [Dept. Paediat., Harvard Med. Sch., Boston, Mass.]

A 10 per cent. solution of protein prepared by fractionation and dialysis of pooled rabbit antisera against pneumococcus type III polysaccharide was injected intravenously into normal rabbits from which an equal volume, 15 to 20 ml., of blood had previously been removed. Subsequent exchange transfusion of normal rabbit blood, or injection of the specific antigen, was followed by the expected fall in circulating antibody, but the circulating antibody then rose rapidly before resuming the logarithmic decline found in rabbits injected with antisera but not otherwise treated. It was concluded that preformed plasma protein in the extra-vascular pool is in dynamic equilibrium with that in the circulation and can rapidly make good depletion of the latter.—W. M. Deans.

MORTENSEN, R. A. The effect of diet on the glutathione content of erythrocytes. *J. Biol. Chem.*, 1953, **204**, 239–243. [Dept. Biochem., Sch. Med., Coll. Med. Evangelists, Loma Linda, Calif.]

Weanling rats received diets deficient in methionine, with soya bean α -protein or extracted peanut meal as protein sources. Controls received Purina chow or the deficient diets with methionine supplement.

Reduced glutathione in the red blood cells was 59 mg. per 100 ml. in controls, but in methionine-deficient rats it rose in 2 weeks to 114 mg. per 100 ml. Liver glutathione was decreased to about a third of its normal value. Addition and withdrawal of methionine supplements produced rapid changes of glutathione level in the red cells. It is suggested that glutathione formed in the liver may be used to maintain red cell glutathione.

GERTLER, M. M. and OFFENHEIMER, B. S. Serum uric acid levels in men and women past the age of 65 years. *J. Gerontol.*, 1953, **8**, 465–471. [Med. Div., Home Aged and Infirm Hebrews, New York.]

The subjects were 38 men aged from 66 to 86 and 91 women aged from 65 to 88 years who were free from diseases known to affect metabolism or retention of uric acid and for whom data are tabulated for uric acid, free and total cholesterol, lipid P, and S_r 10–20 molecules in serum and for ponderal index ($H/3\sqrt{W}$).

There was a sex difference in uric acid content, the mean for men, 4.96 mg., being significantly greater than for women, 4.55 mg. per cent., and nearly twice as many men as women had levels above 6.0 mg. For men correlations of uric acid with total cholesterol, with lipid P and with S_r 10–20 molecules were significant; that with ponderal index was not. For women the correlation of uric acid with ponderal index was alone significant.

Possible explanations of these sex differences are discussed.—D. Harvey.

1944

LINHARD, J., BUSSON, F., GIRAUD, P. and GUYONNET, C. Dosage du calcium sérique. Application à des sérums d'Africains de Dakar. [Estimation of serum calcium: application to the serum of Dakar Africans.] *Méd. trop.*, 1953, **13**, 520-525. [Org. Enquête Étude Anthropol. Pop. Indigènes A.O.F. Aliment. Nutrit.]

In 24 young adult Europeans living in Dakar the mean serum Ca was 9.883, range 9.1 to 10.8, mg. per 100 ml. In 256 apparently healthy male Africans of different races living in Dakar the mean was 9.236, S.D. 0.427, range 8.0 to 11.3. In a series of 37 African women from another place the mean was 9.067, S.D. 0.787, range 7.6 to 11.6. The distribution of values for the African males was normal. No difference between the values for different races of Africans was found. Spasmodophilia was fairly frequent among the Africans studied.—L. Wills.

1945

HOPKINS, T. R., CONNOR, T. B. and HOWARD, J. E. Ultrafiltration studies on calcium and phosphorus in pathological human serum. *Bull. Johns Hopkins Hosp.*, 1953, **93**, 249-268. [Dept. Med., Johns Hopkins Univ., Baltimore, Md.]

Ultrafiltration data, obtained by Laviertes's technique with rigid pH control, are presented for sera from normal subjects and from patients with disorders involving abnormal concentrations of serum Ca, P and protein. No correlation was found between high Ca and high protein values in the diseases studied. In general low protein was associated with low Ca. High ultrafiltrable Ca is considered to be of no differential diagnostic value in hyperparathyroidism, since it was found also with all high Ca values of non-parathyroid origin, and in hyperparathyroidism might not be found unless total serum Ca was also high. With a few exceptions the inorganic P of serum was almost all ultrafiltrable, and similarly, with a few exceptions, the ratio of ultrafiltrable Ca to total serum Ca was within the normal range. This ratio remained relatively constant despite marked changes in total serum Ca produced by therapeutic or surgical means.—M. B. Richards.

LINHARD, J., BUSSON, F. and GIRAUD, P. Dosage du magnésium sérique. Application à des sérums d'Africains de Dakar. [Estimation of serum magnesium: application to the serum of Dakar Africans.] *Méd. trop.*, 1953, **13**, 526-529. [Org. Enquête Étude Anthropol. Pop. Indigènes A.O.F. Aliment. Nutrit.]

Vol. 24, No. 2

Serum Mg was estimated colorimetrically with thiazole yellow in 95 healthy African and 10 European men living in Dakar. The mean serum Mg in Africans was 2.1, range 1.5 to 2.8 mg. per 100 ml.; in Europeans the mean value was 2.15. The distribution of the values in the African series was normal.—L. Wills.

1947

MARTIN, H. E., MEHL, J. and WERTMAN, M. Clinical studies of magnesium metabolism. *Med. Clins. N. Amer.*, 1952, **36**, 1157-1171. [Los Angeles County Hosp., Calif.]

In chronic renal disease serum Mg is generally positively correlated with serum K, though not with serum Na or Ca. In acute renal failure it is raised during oliguria, but falls rapidly during the period of diuresis. In untreated diabetic coma serum Mg is raised, but after treatment it falls rapidly during the marked diuresis; while Mg is high serum K may be low. In conditions such as epilepsy, eclampsia, hyperthyroidism and pancreatitis serum Mg is low, but the mechanism producing this change is not known. No definite sign or symptom could be related to low serum Mg; this is in contrast to the findings in animals, in which Mg deficiency produces neuromuscular changes.—L. Wills.

MUKHERJEE, C. and MUKHERJEE, S. K. **Studies in iron metabolism in anaemias in pregnancy. 2. Iron binding capacity and iron saturation of plasma.** *J. Indian Med. Assoc.*, 1953, **23**, 1-10. [Eden Hosp. Women, Calcutta.]

For part 1, see Abst. 614, Vol. 24.

Tables of frequency distribution with mean values, S.D. and S.E. are presented for Fe-binding capacity and Fe saturation of plasma of 50 normal non-pregnant women, 60 healthy women in the last trimester of pregnancy, 78 patients with Fe-deficiency anaemia, 58 with dimorphic anaemia and 12 with nutritional macrocytic anaemia of pregnancy. Values obtained week by week from the third month of pregnancy in 10 healthy women are presented and the effect is shown of intravenous administration of 25 mg. Fe daily for 1 week to 28 women in the 38th to 39th week of normal gestation.

The increase in Fe-binding capacity and decrease in Fe saturation of plasma observed as pregnancy progresses normally were exaggerated in Fe-deficiency and dimorphic anaemias. In nutritional macrocytic anaemia Fe-binding capacity was somewhat less than and Fe saturation was about the same as in normal pregnancy. In normal pregnant women administration of Fe caused little change in total Fe-binding capacity and an increase in Fe saturation.—F. C. Aitken.

LYMPH, CEREBROSPINAL FLUID, ETC.

1952

BORGSTRÖM, B. and LAURELL, C. B. **Studies on lymph and lymph-protein during absorption of fat and saline by rats.** *Acta physiol. scand.*, 1953, **29**, 264-280. [Dept. Physiol., Univ. Lund.]

Cannulae were inserted into the main lymph vessel draining the small intestine of rats. The animals were then starved for 18 hr. before the administration by mouth of 1.0 ml. maize oil, 10 ml. 0.9 per cent. NaCl or 10 ml. 5.5 per cent. glucose. Lymph was collected for estimation of protein and electrophoretic examination.

The results suggest that lymph flow depends partly on the volume of blood flowing through the small intestine. The flow increased considerably after the administration of maize oil and to a smaller extent after saline or glucose.

Electrophoresis showed that the protein pattern of the lymph was identical with that of plasma and independent of the variations in the protein concentration of the lymph. Fat particles migrated with the same velocity as albumins. Lipoproteins of the type found in plasma did not increase in the lymph during maize oil absorption.

Glutamine in cerebrospinal fluid from 26 patients with neurological disorders ranged from 5.4 to 9.4 mg. per 100 ml. with a mean of 7.35 ± 2.0 . Thirteen of the samples were analysed for glutamic acid, but it was either absent or present only in traces. γ -Aminobutyric acid could not be detected in any of the fluids investigated. No relation could be established between glutamine content and the type of disorder.—W. Godden.

Urinary calculi from 63 steers were qualitatively examined. All contained protein and silica, and frequently Ca and oxalate were present. Mg appeared less frequently and NH_4 , CO_3 and PO_4 ions were rarely found.

It is considered that the calculi may be formed by precipitation of the dissolved silica in the urine (50 to 150 p.p.m.) by mucoproteins. The

N.A. and R., April 1954

conditions governing the form of the precipitation are not known.—P. C. Jowsey.

TISSUES

1959

HAMWI, G. J. and URBACH, S. **Body compartments : their measurement and application to clinical medicine.** *Metabolism*, 1953, **2**, 391–403. [Dept. Med., Div. Endocrinol. Metabol., Coll. Med., Ohio State Univ.]

The methods of investigation are reviewed. Estimates of total and extracellular water were made by antipyrine and thiocyanate methods and lean body mass was calculated from the formula of Pace *et al.* (Abst. 1477, Vol. 15). Mineral matter was taken to be 7 per cent. of lean body mass, and cell solids as the difference between total weight and the sum of fat, water and mineral matter.

Data are tabulated for 5 normal subjects between 36 and 53 years of age, 13 elderly, from 57 to 80 years, 5 each of emaciated, obese and diabetic patients and 2 other patients who had undergone testosterone therapy. Total body water in litres and cell mass in kg. for all subjects showed high degrees of correlation with surface area, $r = +0.89$ and $+0.81$, respectively. The changes which took place after testosterone therapy, increases in total body water and cell mass, were not associated with proportionate increases in weight and surface area. This finding is considered to indicate the value of the technique in the study of metabolic phenomena.—D. Harvey.

FIDANZA, F., KEYS, A. and ANDERSON, J. T. **Density of body fat in man and other mammals.** *J. Appl. Physiol.*, 1953, **6**, 252–256. [Lab. Physiol. Hyg., Univ. Minnesota, Minneapolis.]

Samples of human subcutaneous and internal body fat were obtained from 5 adults during surgical operations. The differences between individuals and between locations were trivial. The mean density at 37° C. from 20 measurements was 0.9 g. per c.cm., S.D. $\pm 6.8 \times 10^{-4}$, S.E. of mean $\pm 1.5 \times 10^{-4}$. The mean modulus of expansion from 15° to 37° C. was 9.2×10^{-4} $\pm 1.3 \times 10^{-4}$. Fat samples from 7 mammalian species were also studied. In 3 dogs the fat did not differ greatly from the human samples. In man, dog, rabbit, rat and guinea-pig subcutaneous and internal samples were similar in composition, but in the steer, the pig and especially

in the lamb subcutaneous fat was less dense than internal. Butterfat had a density similar to that of internal fat from steers.

Sources of error in estimations of total body fat are discussed.—D. Duncan.

1962

REH, H. Die Fettzellgrösse beim Menschen und ihre Abhängigkeit vom Ernährungszustand. [The size of the fat cell in man and its relation to nutritional state.] *Virchows Arch.*, 1953, **324**, 234–242. [Inst. Pathol., Univ. Marburg a.d. Lahn.]

The size of fat cells in 16 subjects could be related to the nutritional state. The average diameter of cells from normal subjects ranged from 70 to 120 μ . Diameters below 70 μ were found in emaciation and above 120 μ in obesity and in patients with lipomas, the largest found being 170 μ . With enlargement in size the fat cells from different sites, and even from the same site, tended to be more variable in diameter.

KUZNETSOV, P. M. Khimiya zhirov ezha (Erinaceus rumanicus). [The chemistry of the fats of the hedgehog (*Erinaceus rumanicus*).] *Biokhimiya*, 1953, **18**, 163–168. [Nauch-Issled. Inst. Khim., Mosk. Gosud. Univ.]

Subcutaneous and body fats from 5 captive hedgehogs (*Erinaceus rumanicus*) and 2 caught wild were analysed. The iodine numbers of the subcutaneous fat were lower than those of the body fat. Of the total mixed subcutaneous fat about 21 to 23 per cent. was solid; stearic acid formed 20 to 22 per cent. of this fraction and palmitic acid the rest. The remaining 78 per cent. of the subcutaneous fat was oleic acid. The fats were triglycerides. Of the 0.35 per cent. of unsaponifiable material 19.8 per cent. was cholesterol.

- HART, P. C. Onderzoek naar het mangaan-gehalte van runderlevers. [**Manganese content of livers of cows.**] *Tijdschr. Diergeneesk.*, 1953, **78**, 929-940. [Inst. Veeteeltk. Onderzoek T.N.O., Utrecht.] English, French and German summaries.

The material analysed was dried liver from 62 cows from an experiment in which half were given methylthiouracil (Vevoron) for 5 weeks during which they were fattened. Mn was estimated as KMnO_4 after acid digestion. Dry liver from control cows contained $10.90 \mu\text{g.}$ per g. and that from cows treated with methylthiouracil $8.44 \mu\text{g.}$ The weight of the liver after methylthiouracil was greater than in control cows, but the total Mn was less. Both differences were significant.

Roentgenographic features of skeletal development in normal and thyroid-ablated infant rhesus monkeys (*Macaca mulatta*).** *Amer. J. Dis. Child.*, 1953, **86**, 426-435. [Dept. Radiol., Univ. California Sch. Med., San Francisco.]

For previous papers see Abst. 643, Vol. 24.

Six monkeys were selected for X-ray study, 4 of them receiving thyroid-ablating doses of ^{131}I , at 22, 35, 122 and 162 days of age, respectively. Three eventually were treated with L-thyroxine at 6 or $20 \mu\text{g.}$ per kg. bodyweight daily. X-ray photographs of the whole body were taken every 30 days.

Within 30 days of thyroid ablation the rate of linear bone growth decreased, in conformity with

the cessation of body growth described in an earlier paper. Bone density increased. The animals which received $20 \mu\text{g.}$ L-thyroxine per kg. bodyweight daily showed resumption of normal bone growth within 30 days, but the one receiving only $6 \mu\text{g.}$ per kg. daily showed a poor response. Epiphyseal centres of maturation appeared late and developed slowly in athyroid monkeys. In the skull there was poor growth, relative and absolute enlargement of the *sella turcica*, delayed closure of sutures, marked overriding of parietal by occipital bones and delayed eruption of deciduous teeth. All the effects responded to treatment with L-thyroxine.—D. Benzie.

- GRAD, B. **Changes in oxygen consumption and heart rate of rats during growth and ageing: role of the thyroid gland.** *Amer. J. Physiol.*, 1953, **174**, 481-486. [Gerontol. Unit, Allan Mem. Inst., Montreal.]

Oxygen consumption and heart rate were studied in rats continuously from birth to old age as described in Abst. 141, Vol. 22. The lowest values occurred at birth, the highest a month later, after which they declined gradually as the rats aged. This fall towards the end of life was due, at least partly, to diminished ability to react

N.A. and R., April 1954

to thyroid hormone. After thyroid removal rats did not show the decline in heart rate and oxygen consumption with ageing, because of the great fall in the rate of both functions immediately after the operation. Male rats had a higher oxygen consumption than female if calculated per unit of metabolic size, *i.e.*, per kg.^{0.75} bodyweight, but there was no significant difference when calculated per unit bodyweight. Males had a higher heart rate calculated on equivalent bodyweights, but without this adjustment there was no difference between the sexes.—B. W. Simpson.

1974

PICHOTKA, J., KÜGELGEN, B. v. and DAMANN, R. Die Bedeutung der Schilddrüse für die Temperaturregulation. [**Importance of the thyroid for temperature regulation.**] *Arch. exp. Pathol. Pharmacol.*, 1953, **220**, 398–413. [*Physiol. Inst., Freiburg i. Br.*]

Deprivation of thyroid function, either by thyroidectomy or treatment with thiouracil, interferes seriously with temperature regulation in the guineapig. This was demonstrated by measuring the rate of decrease in rectal temperature when the animals were placed in a cold chamber at -1.5°C . For normal animals the temperature curves showed a steep initial fall, followed by a more or less prolonged flattening between 37° and 33° and a steeper fall below 33°C . In animals deprived of thyroid function the curves showed a continuous steep fall, with none of the flattening between 37° and 33°C . which is an expression of temperature-regulating efficiency. In animals treated with propylthiouracil for 15, 20 or 28 days the temperature curves during the cooling process showed increasing deviations from the normal with increasing length of medication. After 28 days' treatment the steepness and uniformity of the fall were even more pronounced than after thyroidectomy. The average times taken to reach a body temperature of 30°C . for 10 normal, 5 thyroidectomised, and 12 thiouracil-treated animals were 122, 49 and 39 min., respectively. During the cooling process oxygen intake in a normal animal increased from 6 to 20 ml. per min., in an animal treated with thiouracil for 3 weeks from 6 to 9 ml., and in a thyroidectomised animal from 4 to 6 ml. Thus the amount of energy which thyroid-deprived animals can produce to prevent the disturbance of temperature is only a fraction of the normal.—M. B. Richards.

1975

WASE, A. W., EICHEL, H. J. and REPPLINGER, E. **Relation of thyroid status to nitrogen excretion following exposure to thermal radiation.** *Proc. Soc. Exp. Biol. Med.*, 1953, **84**, 152–154. [*Div. Vol. 24, No. 2*]

Biol. Chem., Hahnemann Med. Coll., Philadelphia, Pa.]

Groups of 12 adult male rats were fed on a ration containing 18 per cent. protein. One group received 0.5 per cent. dried thyroid, another group 0.5 per cent. thiouracil. The third group served as controls. The status of the thyroid glands was confirmed by measuring the uptake of ¹³¹I before and after exposure to radiant heat. The rats were pair-fed and 3-day N balances started on the 21st and 28th days of experiment. All groups were in similar states of negative N balance. On the 34th day half the rats in each group were subjected to burning and a third N balance was begun.

The hyperthyroid burned rats excreted 50 per cent. more urinary N and 19 per cent. more total N than the hyperthyroid unburned rats. The control, euthyroid burned rats excreted 131 per cent. more urinary N than the unburned controls and 47 per cent. more total N, and their negative N balance increased by 57 per cent. In the hypothyroid group there was little change in the condition after burning.

It is suggested that the probability of other endocrine functions being involved in the initiation or perpetuation of abnormal protein catabolism after severe burns cannot be ruled out.

B. W. Simpson.

1976

LONG, J. F., HIBBS, J. W. and GILMORE, L. O. **The effect of thyroprotein feeding on the blood level of inorganic iodine, protein-bound iodine and cholesterol in dairy cows.** *J. Dairy Sci.*, 1953, **36**, 1049–1057. [*Dept. Dairy Sci., Ohio Agric. Exp. Stat., Columbus.*]

Dairy cows received thyroprotein at rates of 10, 15, 20 and 25 g. per 1000 lb. bodyweight daily. Changes in serum protein-bound iodine and plasma cholesterol were followed during and after treatment. Inorganic I and blood sugar were also estimated.

During treatment protein-bound I rose to a level above that expected from the clinical evidence of hyperthyroidism. Plasma cholesterol decreased for a time during treatment and then returned to normal. It rose above normal after the end of thyroprotein feeding and then gradually returned to normal. Inorganic I also increased during treatment. Blood sugar was unchanged. Neither plasma cholesterol nor protein-bound I could be closely correlated with the dosage of thyroprotein, though it was concluded that protein-bound I does reflect thyroid status.—J. N. Aitken.

MELLEN, W. J. and HILL, F. W. **Effects of thiouracil, thyroprotein, and estrogen upon the basal metabolism and thyroid size of growing**

chickens. *Poultry Sci.*, 1953, **32**, 994-1001. [Dept. Poultry Husb., Cornell Univ., Ithaca, N.Y.]

Groups of 20 male day-old chicks were given a commercial starter basal ration with or without dienoestrol diacetate 0.005, thiouracil 0.1 and protamone 0.02 per cent., singly or together.

Protamone caused a highly significant depression of basal metabolic rate (B.M.R.) without decreasing the growth rate. It is suggested that this may have been because the chicks were in a temporary state of hypothyroidism during B.M.R. estimation, as they had been starved for at least 34 hr. beforehand. Thiouracil depressed growth and O_2 consumption, but had no effect on B.M.R. when the latter was corrected for bodyweight. The effect of the oestrogen was to increase the B.M.R. slightly and to neutralise the effect of thiouracil on growth.—M. J. Head.

BURRIS, M. J., BOGART, R. and KRUEGER, H. **Alteration of activity of thyroid gland of beef cattle with testosterone.** *Proc. Soc. Exp. Biol. Med.*, 1953, **84**, 181-183. [Dept. Animal Husb., Oregon Agric. Exp. Stat., Corvallis.]

A group of 6 heifers and 6 steers received no testosterone; animals of a similar group were injected intramuscularly with 1 mg. testosterone per kg. bodyweight. The average daily gain and feed requirement per unit gain for individual animals were recorded during growth from 500 to 800 lb. liveweight. When each animal reached 800 lb. it was slaughtered. The thyroids of 2 heifers and 2 steers in each group were macerated and injected into mice which had had for 4 weeks a ration containing 0.1 per cent. thiouracil. The mice were killed 36 hr. later; the time required for death by asphyxiation was used as an indication of the activity of the thyroids.

The cattle which had received testosterone had larger and more active thyroids with a lower hormone content than controls. The average daily weight gain of the control heifers was 2.09 lb. and that of the testosterone-treated heifers 2.61 lb. Gains for the steers were 2.65 and 2.74 lb., respectively, the differences being statistically significant.—B. W. Simpson.

ENERGY EXCHANGE AND SPECIFIC DYNAMIC ACTION

1981

KULIN, L. Eine neuartige Auffassung der Pathogenese der Säuglingsatrophie und die daraus abgeleitete Therapie. [A new concept of the pathogenesis of atrophy in infants, and the derived treatment.] *Ann. Paediat.*, 1953, **181**, 320-326. [Kinderklin., Univ. Debrecen.] English and French summaries.

It is suggested that the fundamental cause of atrophy in infants is disparity between anabolism and catabolism. Because of the excessive proportion of surface area to bodyweight, which becomes more marked as atrophy increases, there is increased loss of heat, for which the infant must compensate with a considerable part of his total energy output, so that weight increase is impossible. Since the capacity for assimilation is diminished the increased energy requirement cannot be met by increasing the food intake. The only practicable way is to diminish the loss of heat from the body surface and thus relieve the organism of the necessity of meeting the heat requirements from the food. If the infants are kept in air-conditioned

chambers at a temperature of 28° to 33° C., with a relative humidity of 55 to 70 per cent., the energy thus saved by heat regulation can be utilised for assimilation and weight increase. These theories were confirmed by results attained with 24 atrophic infants who had been treated without success for different periods at an average room temperature of 22° C. When they were brought into warm moist surroundings, 17 responded immediately, and the remaining 7 within a few weeks, with a constant ideal weight increase.—M. B. Richards.

1982

GARN, S. M., CLARK, L. C. (Jr.) and PORTRAY, R. **Relationship between body composition and basal metabolic rate in children.** *J. Appl. Physiol.*, 1953, **6**, 163-167. [Fels Res. Inst., Antioch Coll., Yellow Springs, Ohio.]

Estimates of body muscle and fat were obtained, by measurement from X-ray photographs made under standard conditions, of the lower leg and of the deltoid region of 49 boys and 46 girls aged 6 to 18 years. The estimated values, combined,

N.A. and R., April 1954

were found to be correlated with basal oxygen consumption, the coefficients being $+0.79 \pm 0.06$ and $+0.67 \pm 0.09$, for boys and girls, respectively.

DRAPER, J., EDWARDS, R. G. and HARDY, R. H. **Method of estimating the respiratory cost of a task by use of minute-volume determinations.** *J. Appl. Physiol.*, 1953, 6, 297-303. [Clothing and Equipment Physiol. Res. Establishment, Minist. Supply, S. Farnborough, Hants.]

Respiratory minute volume, in litres, was measured from the total expired air of 2 successive 5-min. periods, in 9 men carrying loads of from 4 to 16 kg. on the back and from 0.6 to 2.4 kg. on the feet. The slopes of the regression lines of minute volume on weight carried on the back, and on weight carried on the feet, respectively, were $+0.400 \pm 0.039$ and $+0.926 \pm 0.158$. It is indicated that this might be a simple method of assessing the metabolic cost of a task. [No relation is given between minute volume and absolute energy expenditure.]—S. D. Morrison.

1985

COLE, P. **Further observations on the conditioning of respiratory air.** *J. Laryngol. Otol.*, 1953, 67, 669-681. [Dept. Physiol., Univ. Manchester.]

The results of experiments on a normally clothed subject at rest, breathing air at different temperatures and humidities, are presented graphically. It was concluded that losses from the respiratory tract form from 10 to 20 per cent. of total body heat and water loss; in temperate conditions, at a ventilation rate of 10 litres per min., from 250 to 350 Cal. and from 300 to 400 ml. water per 24 hr.—W. M. Deans.

1986

VIGLIANI, E. C. and PASARGIKLIAN, M. Sul consumo energetico e sul rendimento respiratorio durante lavoro muscolare protratto. [Consumption of energy and respiratory activity during prolonged muscular work.] *Med. del Lavoro*, 1953, 44, 313-324. [Clin. Lavoro "Luigi Devoto", Univ. Milan.] English summary.

Four subjects performed a series of marches at rates of 0.8 to 7 km. per hr. on different gradients, for periods of up to 5 hr., with a portable ergometer. The air inspired was measured with a Tissot's spirometer and analysed every 30 to 60 min. with a Haldane apparatus. It was concluded that when the energy required by work is less than 8 Cal. per hr. per kg. bodyweight, the mechanical efficiency and the respiratory power are unaffected by the time of work and maintain their initial value for the duration of the test; that when the energy required by work is more than 8 Cal. per hr. per kg. bodyweight, the energy expenditure and respiratory ventilation increase with the prolongation of work so that mechanical efficiency and respiratory energetic power are progressively reduced. Therefore muscular work up to the intensity of 8 Cal. per kg. bodyweight per hr. can be carried out continuously for many hours (certainly for 5 hr.), whereas when the intensity of work is greater, fatigue sets in and is increased by a rise in the work intensity or by prolongation of the time of work. (From summary.)

MÜLLER, E. A. **The physiological basis of rest pauses in heavy work.** *Quart. J. Exp. Physiol.*, 1953, 38, 205-215. [Max-Planck Inst. Arbeitsphysiol., Dortmund.]

In this lecture are described the methods and apparatus used in the Max-Planck Institute to determine the length and number of pauses required in heavy work. One method is to give sufficient pauses to keep the average energy expenditure over the whole shift at a level of 4 Cal. per min., which is taken as the limit of working capacity. This method is crude, since the limit of energy expenditure differs for different patterns of work and for individuals with different degrees of muscular training. A more reliable method depends on measurement of pulse rate as an index of sufficient blood supply to the muscles, the chief necessity in avoiding fatigue. The aim is to keep the pulse rate during the shift at a constant average level. If work is done above the endurance limit, the pulse rate continues to rise, fatigue increases, and the recovery period is prolonged. This method has proved useful in arranging pauses so that a man may work within his endurance

limit. The pauses must be real pauses and any kind of movement retards recovery.

DE WIJN, J. F. and VAN LEEUWEN, P. De bijdrage van eiwitten, koolhydraten en vetten aan de totale calorische opnemings bij zware en lichte arbeid. [Contribution of proteins, carbohydrates and fats to total energy intake in heavy and light work.] *Voeding*, 1953, 14, 504-508. [Nederl. Inst. Praevent. Geneesk., Leyden.] English summary.

Analysis of the diets of 61 workers showed that 13 administrative, technical and laboratory workers had energy intakes between 2700 and 3300 Cal. and 1 had 4000 Cal.; 27 instrument makers had from 2300 to 4700 Cal. and of 20 heavy workers only 2 had less than 3300 Cal. There was no difference between groups arranged by energy intake in respect of the percentage of calories from protein; the mean was 12.0 per cent.—I. Leitch.

HETTINGER, T. and WIRTHS, W. Über die körperliche Beanspruchung beim Hand- und Maschinenmelken. [Energy expenditure in hand and machine milking.] *Arbeitsphysiologie*, 1953, 15, 103-110. [Max Planck Inst. Arbeitsphysiol., Dortmund.]

A study was made with one woman milker managing a herd of 12 cows, of the relative pulse rate and energy expenditure in milking by hand and with a machine having 2 teat cups. The whole process, including hand stripping after machine milking and the work of preparing and cleaning the milking utensils, was studied. With machine milking there was a saving of 6 per cent. in time as compared with hand milking and 7.5 to 30 per cent. less increase in energy exchange and in pulse rate over the resting rates. It is considered that by further improvements in milking machines it should be possible to reduce the fatigue of milking still further.—W. Godden.

BAL, M. E. R., THOMPSON, E. M., MCINTOSH, E. M., TAYLOR, C. M. and MACLEOD, G. Mechanical efficiency in cycling of girls six to fourteen years of age. *J. Appl. Physiol.*, 1953, 6, 185-188. [Nutrit. Lab., Teachers Coll., Columbia Univ., New York.]

The energy expenditure in standard cycling on a bicycle ergometer was measured in 54 trials on 18 girls. Net efficiency was estimated from measured values of basal energy expenditure and of energy expenditure of the girls sitting quietly. The efficiencies at each age were slightly less than those previously reported for boys (Abst. 3685, Vol. 20).—S. D. Morrison.

YOUNG, C. M., RINGLER, I. and GREER, B. J. Reducing and post-reducing maintenance on the moderate-fat diet. *Metabolic studies. J. Amer. Dietetic Assoc.*, 1953, 29, 890-896. [Sch. Nutrit., Cornell Univ., Ithaca, N.Y.]

Six young college women, 11 to 48 per cent. overweight, were given for 10 weeks a reducing diet supplying 1400 Cal., 90 g. protein, 80 g. fat and 80 g. carbohydrate. During the next 5½ weeks energy intake was increased until there was no loss of weight. All diets contained 1 g. Ca and 1.5 g. P daily and met or exceeded the U.S. National Research Council allowances of other nutrients. B.M.R. and N, Ca and P balances were estimated near the beginning and end of reducing and in the fourth week of the post-reducing period.

In 10 weeks the subjects lost from 14 to 26 lb. The B.M.R., which fell by 8 per cent. between the first and second estimations, was still low after 4 weeks on the maintenance diet. Most subjects were in negative Ca, P and N balance at the end of reducing, but 4 weeks later all were in retention or balance for N and only one subject remained in negative Ca or P balance.

There was a tendency for fasting blood lipids to increase somewhat during weight reduction and slightly thereafter.

Possible advantages of a step-wise reducing regimen are considered.—F. C. Aitken.

SHUMSKII, P. I. Vliyanie kratnosti kormleniya na uglevodnozhirovoi obmen u rabotayushchikh loshadei. [The effect of frequent feeding on carbohydrate-fat metabolism in working horses.] *Konevodstvo*, 1953, No. 6, 16-20. [Opyt. Konnyi Zavod VNIIEK.]

Six horses aged 7 to 10 years, in 2 groups, were fed 3 times during the night. During the day 1 group was fed only during the dinner hour, the other 3 times and 4 times during 10- to 15-min. intervals of work. Oxygen and CO₂ were estimated in the expired air. More frequent feeding increased the proportion of carbohydrate metabolism and reduced fat metabolism.

In the first test the horses were fed on a mixture of 52 to 70 kg. vetch and oats, in the second on 8 to 9½ kg. oats and 11 to 16 kg. hay. In the first test, among the horses fed 6 times daily, the percentage of carbohydrate metabolised in 6 hours' work was 44.69, among those fed 4 times, 34.67. In the second test in 6 hours 40 minutes' work the proportions were 37.39 and 29.03 per cent. The 10 to 15 minutes' extra feeding had a stimulating effect on metabolism, especially of carbohydrates.

McDOWELL, R. E., LEE, D. H. K., FOHRMAN, M. H. and ANDERSON, R. S. **Respiratory activity as an index of heat tolerance in Jersey and Sindhi × Jersey (F₁) crossbred cows.** *J. Animal Sci.*, 1953, **12**, 573-581. [Bur. Dairy Indust., U.S. Dept. Agric., Beltsville, Md.]

Two groups of 20 purebred Jersey and 20 Red Sindhi × Jersey cows were used. The groups were similar in age, bodyweight, reproductive state and level of production. Initial measurements of

rectal temperature, respiratory rate and respiratory volume were made at normal temperatures, 57° to 84° F. The cows were then exposed to a temperature of 105° F. with a vapour pressure of 34 mm. Hg. for 3 hr., during which time they received no feed or water.

The heat tolerance of the crossbred cows proved superior to that of the purebred Jerseys. The respiratory volume of the Jerseys was higher and increased to a greater extent than that of the crosses. The rectal temperature of the purebred Jerseys also rose significantly above that of the crosses, despite the additional cooling effect to be expected from the increased respiratory volume. There was a highly significant positive correlation between rectal temperature and respiratory volume, except in lactating animals maintained at normal temperatures.

It was concluded that the superior heat tolerance of the crosses could not be ascribed to greater respiratory response, but the increased respiratory activity of the pure Jerseys was an attempt to compensate for a poor heat balance due to some other cause. There was no significant correlation between respiratory rate and rectal temperature.

The method of measuring respiratory volume is described in detail.—J. N. Aitken.

WORSTELL, D. M. and BRODY, S. **Environmental physiology and shelter engineering with special reference to domestic animals. 20. Comparative physiological reactions of European and Indian cattle to changing temperature.** *Missouri Agric. Exp. Stat. Res. Bull.* No. 515, January 1953, pp. 42. [Columbia, Mo.]

This is a statistical study of the more significant physiological data already published on the effect of temperature while other climatic conditions are constant (*cf.* Absts. 1789, 1840, Vol. 23; 5049, Vol. 21). It is concerned with the mechanisms involved in regulating the internal body temperature in the face of changing environmental temperature. Jersey, Holstein and Brown Swiss represented the European cattle and Texas-bred Brahman the Indian cattle. Data obtained in 5 experiments during periods of increasing temperature from 50° to 105° F. and decreasing temperature from 50° to 5° F. are included. Except at high temperatures the cows were kept at each temperature level at intervals of 5° or 10° F. for about 2 weeks.

Normal body temperature was maintained without serious aid from physical or chemical homeothermic mechanisms between about freezing and 60° F., but the precise range depended on the productive level. The higher the productive level and the larger the individual, the greater the cold tolerance and the lower the heat tolerance.

Fall in temperature to near 0° F. had no effect on the heat production of Holstein cows, but increased both heat production and feed consumption in the Brahmans and to some extent in the Jerseys. The declining temperature gradually reduced the rates of respiration, pulmonary ventilation and moisture evaporation in the European cows. No other change was observed. Rising temperature affected the European animals profoundly above 60° F., when the respiration and moisture evaporation rates were suddenly accelerated, reaching a maximum at about 85° F. Rectal temperature in high-producing European cows began to rise at about 70° F. and this was followed by decrease in feed consumption, milk production, heat production, pulse rate, blood CO₂-combining power and ascorbic acid content, and increase in blood creatinine. This low heat tolerance appears to be associated with low moisture vaporisation and high heat production relative to surface area. The Brahman cows lagged behind the European cows by about 15° F. before a rise of rectal temperature and other physiological reactions appeared, owing to their 12 per cent. greater surface area per unit weight and lower heat production. As the environmental temperature approached 105° F. the distress of Indian cows approached that of European cows. Brown Swiss cows, although of the same body-weight and milk yield as Holsteins, appeared to be much more tolerant of heat. There appears to be more urgent need for protecting cattle against temperatures above 80° F. than against temperatures below freezing or even 0° F.

KIBLER, H. H. and BRODY, S. **Environmental physiology and shelter engineering with special reference to domestic animals. 22. Influence of humidity on heat exchange and body temperature regulation in Jersey, Holstein, Brahman and Brown Swiss cattle.** *Missouri Agric. Exp. Stat. Res. Bull.* No. 522, April 1953, pp. 35.

Methods of measurement and apparatus employed have already been described (Absts. 578, Vol. 20; 2150, Vol. 21). Changes in atmospheric humidity at constant temperature levels of 12° and 40° F., and at air velocity of about $\frac{1}{2}$ mile per hr., produced no consistent effect on heat production, evaporative cooling from the respiratory tract and body surface, rectal temperature, respiration rate, pulse rate or pulmonary ventilation rate in Jersey and Holstein cattle. Increasing atmospheric humidity increased the rectal temperature in Jersey, Holstein and Brown Swiss cows and Brahman cattle at environmental temperatures above 75° F. and above 90° to 95° F., respectively; increased the respiration in the first 3 breeds at above 85° F. and in Brahman cattle at above 90° to

95° F.; increased pulmonary ventilation rate at 85° to 100° F. in Jersey, Holstein and Brown Swiss cattle and at 95° to 100° F. in Brahman cattle; produced no consistent effect on pulse rate; depressed heat production in all cattle at 85° F. and depressed respiratory vaporisation rate at temperatures above 85° F., particularly in Holstein and Brown Swiss; and depressed vaporisation rate from the skin or outer surface in Jersey, Holstein and Brown Swiss cattle at temperatures from 75° to 95° F. and in Brahmans above 90° to 95° F.—W. Godden.

BARISSON VILLARES, J. and BERTHET, L. A. *Climatologia zootécnica. 13. Contribuição para a demonstração do funcionamento das glândulas sudoríparas nos *Bos taurus* e *Bos indicus*.* [Climatology of animal production. 13. Contribution to demonstration of the function of sweat glands in *Bos taurus* and *Bos indicus*.] *Bol. Indust. animal, São Paulo*, 1952, **13**, 25–36. [Div. Zootec. Nutrição Animal.] English summary.

The presence of moisture and of chloride on the skin of cattle was demonstrated by application to the surface, depilated and washed with distilled water, of iodine and then a mixture of soluble starch in castor oil, or of paper impregnated with a 3 per cent. solution of silver nitrate. The appearance of blue spots or a precipitate of silver oxide indicated the passage of water or chloride out of the skin, mostly round the hair follicles, and is interpreted as showing that the sweat glands do function. Cattle tested were 10 different pure- or crossbred *Bos taurus* and 8 *Bos indicus*. Temperatures were from 22.6° to 33.0° C., under cover, and relative humidity from 63 to 75.—I. Leitch.

GRAF, G. C. and PETERSEN, W. E. **Changes in respiration and heart rates, body temperatures, plasma lactic acid levels and plasma creatinine levels caused by stress in dairy cattle.** *J. Dairy Sci.*, 1953, **36**, 1036–1048. [Dept. Dairy Husb., Univ. Minnesota, St. Paul.]

The effects of low environmental temperature, exercise, intermittent electrical stimulation, dehorning, adrenaline injection and parturition on body temperature, respiration and heart rates and blood lactic acid and creatinine levels in cattle were studied in 12 sets of identical twins and 2 of identical triplets. Not all were subjected to each treatment. One of each set was used as a control.

When animals were exposed to outside temperatures from +16° to –16° F. heart rates increased by 12.4 per cent. and blood lactic acid by 36.4 per cent. Temperature increased by 0.8° F. Vigorous exercise for 10 min. caused significant increases in

N.A. and B., April 1954

respiration and heart rates, and lactic acid increased on the average by 272.7 per cent. Plasma creatinine levels were unaffected. Electrical stimulation increased heart rate, but had no effect on plasma creatinine. Heart rate was also increased by dehorning.

Injection of 1 or 2 ml. adrenaline caused a significant increase in blood lactic acid. An increase in heart rate 15 sec. after injection was followed by a decrease after 60 sec. Respiration rate decreased.

Respiration and heart rates, temperature and plasma lactic acid increased on the day of calving, but quickly returned to normal.—J. N. Aitken.

LYON, J. B. (Jr.), DOWLING, M. T. and FENTON, P. F. **Studies on obesity. 2. Food intake and oxygen consumption.** *J. Nutrition*, 1953, **51**, 65-70. [Brown Univ., Providence, R.I.]

Male mice of C_{57} and C_3H strains were fed individually and to appetite on a diet of casein 30, maize oil 5, salt mixture 5 and dextrin 60 per cent., or the same with three-quarters of the dextrin replaced by Crisco. There were 12 mice of each strain on each diet. Food intake was recorded for 9 days at the outset and again at 5 to 6 months, and oxygen consumption was estimated at ages between 55 and 85 and between 120 and 135 days.

Voluntary energy intake was higher on the diet with 50 per cent. than on that with 5 per cent. fat. On both diets C_3H mice consumed more food daily than C_{57} mice, and they gained weight more rapidly. For weanling mice efficiency of food utilisation was higher on the high-fat diet; there was no strain difference. At the later age this comparison could not be made because the weight range of the animals was too great. With the low-fat diet there was no significant strain difference in oxygen consumption. C_{57} mice on the high-fat diet consumed significantly more oxygen than C_{57} mice on the low-fat diet. There was no such difference in the C_3H mice, in which, as was shown in the previous paper (Abst. 4867, Vol. 23), the extra energy consumed was deposited as carcass fat.—W. M. Deans.

DESMOND, M. M. **Observations related to neonatal hypoglycemia.** *J. Pediat.*, 1953, **43**, 253-262. [Dept. Paediat., Baylor Univ. Coll. Med., Houston, Tex.]

Vol. 24, No. 2

In full term and premature newborn infants blood sugar rose in response to adrenaline. The increase was smaller and less rapid in the first few days of life than at the end of the first week. The response to intravenous glucose was within the normal limits for older children and adults and serum inorganic P did not fall appreciably. Blood glycogen levels were within the normal adult range. No relation could be demonstrated between the eosinophil and blood sugar responses to adrenaline. These observations are discussed in relation to the origin of neonatal hypoglycaemia.—F. C. Aitken.

[The glucose tolerance test with simultaneous estimation of glucose and pyruvic acid in the blood in diabetic persons.] *Presse méd.*, 1953, **61**, 1379-1380. [Paris.]

Glucose and pyruvic acid were estimated in fasting blood samples and in samples taken 30, 60, 90 and 120 min. after administration of 50 g. glucose by mouth.

In 9 normal subjects, blood glucose and pyruvic acid increased together, but the peak of glucose concentration was at about 30 min. and that of pyruvate at 60 min. The mean fasting pyruvate was 7.6 mg. per 1000 g. and the peak never exceeded 12.8 mg. In 14 of 25 diabetics the fasting pyruvate was 10.6 mg. and the peak not more than 13 mg., despite a mean fasting blood sugar of 2.15 g. per 1000 g. In the other 11 the fasting pyruvate was 14 mg. and the level gradually rose after glucose administration to 15.6 mg. at 150 min., whereas the blood sugar rose from its fasting level of 3.09 g. to a peak of 4.34 g. at 60 min. and thereafter declined. Clinical examination showed that the subjects with low blood pyruvate were moderately insulin-sensitive, only one had had coma, and 4 were familial diabetics. Among those with high pyruvate 9 were receiving insulin and were insulin-resistant, coma was relatively frequent and none came from a diabetic family. The significance of the 2 types of diabetes is discussed.

The influence of glucose and fructose on N metabolism was studied in 5 infants aged from 5 to 11 weeks, who were given a synthetic diet in which the only carbohydrate was the sugar in question. The results indicated that fructose given by mouth was in no way superior to glucose in N-sparing effect. In 3 of the infants no significant difference was found between the sugars in the urinary excretions of N, amino-N and amino-acids, but in 2 the total urinary N was 620 and 1450 mg. higher in 3 days of fructose feeding than with glucose; the baby with the highest N excretion had also a distinctly higher excretion of amino-N, histidine, threonine and tryptophan. The weight increase of the children in 6 days was higher with glucose than with fructose. In a

second series of experiments the urinary N excretions in 2 out of 3 infants were about 800 and 840 mg. less in 3 days with glucose than with fructose. M. B. Richards.

SOLDATENKOV, P. F. Obmen sakhara i glikogena mezhdru krovyu kishechnikom i pechenyu u ovets. [The exchange of sugar and glycogen between blood, intestine and liver in the sheep.] *Fiziol. Zh. S.S.S.R. Sechenova*, 1953, **39**, 96-99. [Kaf. Fiziol. Sel'skhoz. Zhivot., Sel'skhoz. Inst., Sverdlovsk.]

Sugar and glycogen exchange between the walls of the digestive tract and the blood, and also between the liver and the blood, occurs rhythmically in sheep 18 to 23 hr. after feeding. Transfer of sugar from liver to blood is usually accompanied by removal of glycogen from the blood. Transfer of sugar or glycogen from the digestive tract to the blood is accompanied by removal of sugar or glycogen, respectively, by the liver. The digestive tract and liver of sheep on an "empty stomach" retain glycogen and do not give it up to the blood. (From author's summary.)—W. Hughes.

JARRETT, I. G. and POTTER, B. J. Insulin tolerance and hypoglycaemic convulsions in sheep. *Austral. J. Exp. Biol. Med. Sci.*, 1953, **31**, 311-318. [Div. Biochem., C.S.I.R.O., Univ. Adelaide, S. Australia.]

Large amounts of insulin given intravenously to normal adult sheep fasted for 1 to 4 days reduced the blood sugar to less than 10 mg. per 100 ml., but even when this low level was maintained for 15 to 18 hr. convulsions were not induced. In 2 adult sheep and 3 lambs in which the adrenals

were denervated insulin sensitivity was increased and convulsions could be produced by quite small doses of insulin, *e.g.*, 4 units per kg. bodyweight in adults. In normal lambs sensitivity was high a few hours after birth, but decreased with age.

Subcutaneous administration of insulin in adults and lambs was more effective than intravenous injection. Of 17 adult sheep given subcutaneously 3 to 5 units per kg., 14 had convulsions and 8 of these failed to recover despite treatment with glucose. The other 3 became comatose. On 3 occasions when the sheep was apparently approaching an irreversible state, usually refractory to glucose treatment, a better clinical response resulted from simultaneous injection of glucose and adrenaline.—D. Duncan.

MURRAY, H. C. and ROSENBERG, M. M. **Studies on blood sugar and glycogen levels in chickens.** *Poultry Sci.*, 1953, **32**, 805–811. [Dept. Foods and Nutrit., Univ. Hawaii, Honolulu.]

The average blood sugar value of 34 mature pullets was found to be 182.5 mg. per 100 ml., falling to the significantly lower value of 159.6 after 3 hr. fasting, but not significantly lower during a further 13 hr. When birds that had been fasted for 16 hr. were fed, the blood sugar rose within 1 hr. from the fasting level of 148 to 176 mg. per 100 ml. No difference in blood sugar was observed with different rations.

Six-week-old cockerels were fasted for 16 hr. and were then given cracked yellow maize or low-grade sugar to appetite. Glycogen was estimated in chicks killed hourly for 10 hr., on livers, breast and lower thigh muscles, none of which contained glycogen at the end of the fast. The glycogen content of the livers of birds fed on maize rose to 6.07 per cent. after 7 hr. and then fell slightly; the livers of those fed on sugar contained 10.33 per cent. glycogen after 10 hr. The glycogen values of the muscles showed no difference attributable to the ration.—M. J. Head.

BAKER, D. G. and SELLERS, E. A. **Carbohydrate metabolism in the rat exposed to a low environmental temperature.** *Amer. J. Physiol.*, 1953, **174**, 459–461. [Dept. Physiol., Univ. Toronto, Ont.]

In rats acclimatised to cold at 1° to 3° C., the glycogen content of heart, liver, diaphragm and

fat from perirenal and interscapular regions was less than in controls kept at room temperature, but the difference in the diaphragm was not significant. The glycogen content of skeletal muscle did not differ significantly in the two groups, which suggested that the level of muscle glycogen was maintained at the expense of liver glycogen reserves. During the process of acclimatisation and the entire period of observation no great change occurred in blood sugar level. Insulin administration caused a greater reduction of blood sugar in animals exposed to cold than in controls, at dose levels from 0.1 to 0.6 unit per 100 g. bodyweight. These results are probably related to the greatly increased rate of metabolism in animals exposed to cold and the associated increase in utilisation of carbohydrate.—M. B. Richards.

REISS, O. K. and BARRY, J. M. **The synthesis of lactose from glucose in the mammary gland.** *Biochem. J.*, 1953, **55**, 783–785. [Dept. Biochem., Univ. Chicago.]

Glucose labelled uniformly with ¹⁴C was injected intravenously into a goat giving about 1 litre of milk daily. Milk and blood samples were taken at intervals during the next 12 hr.

The specific activities of the glucose and galactose fractions of each lactose sample were the same. The activity of the lactose, after it reached its peak at 1 to 2 hr. after the injection, was always equal to that of the blood glucose about 1 to 1.5 hr. earlier.

It is concluded that blood glucose is the precursor of both glucose and galactose residues of milk lactose.—D. Duncan.

LANG, K. and PFLEGER, K. **Über die Verwertbarkeit von Lichenin durch den tierischen Organismus.** [Utilisation of lichenin by the animal organism.] *Biochem. Ztschr.*, 1953, **324**, 530–535. [Physiol. Chem. Inst., Johannes Gutenberg Univ., Mainz.]

When lichenin replaced the 70 per cent. of starch in a ration for rats they ceased to grow and 6 out of 10 died in the first 14 days. The lichenin was not utilised as a source of carbohydrate and the mucous membranes of the rat's intestine did not contain any lichenase. Only a small amount of lichenin was recovered in the faeces, most of it being degraded by intestinal bacteria. When lichenin was given to alloxan-diabetic rats there was no extra excretion of glucose. Lichenin administered parenterally was stored in the leucocytes and the reticulo-endothelial system of the liver.—W. Godden.

CHINN, A. B., LAVICK, P. S., BABB, L. I., BUCKALOO, G. W., STITT, R. M. and ABBOTT, W. E. **Blood isotope levels following a test meal of ^{131}I -labelled protein.** *J. Lab. Clin. Med.*, 1953, **42**, 377-379. [Dept. Med., Sch. Med., W. Reserve Univ., Cleveland, Ohio.]
For previous papers see Abst. 3068, Vol. 23, and Chinn *et al.* (*New Engl. J. Med.*, 1952, **247**, 877). The test meal was similar to that described in the second of these, but albumin labelled with ^{131}I was substituted for labelled casein and gelatine for inactive casein. Each patient received 0.5 g. gelatine per kg. bodyweight and 100 μC . labelled albumin. Blood samples were taken 1, 2 and 3 hr. after the test meal.
In 9 normal subjects and 7 who had undergone subtotal gastrectomy at least 10 per cent. of the isotope was in the blood at the second hour, and all but one showed maximum activity in the blood within 3 hr. None of the 3 patients with pancreatic insufficiency showed more than 3 per cent. of the dose in the blood. It is thought that the method offers a simple procedure for detection of defects in both rate and extent of protein digestion or absorption.—D. Duncan.

[Max Planck Inst., Arbeitsphysiol., Dortmund.]
Earlier work (see Abst. 5073, Vol. 19; 2173, Vol. 20) suggested that trained subjects could not be maintained in a state of fitness for heavy work on 1 g. protein per kg. bodyweight daily. Another study is now reported on 2 well fed subjects trained on an abundant diet with 2 g. protein per kg. bodyweight so that they doubled their muscular power in 3 months. During that time 8.3 kg. of protein tissue was laid down, as estimated from N balances. During the next 80 days, with only 1 g. per kg. bodyweight, protein stores were further increased by 1.5 kg., and in the following 49 days with only 0.8 g. per kg. N equilibrium was maintained without loss of weight or of muscle power.

WATERHOUSE, C., KEUTMANN, E. H. and FENNINGER, L. D. **The use of modified globin as a protein supplement in normal individuals.** *J. Clin. Invest.*, 1953, **32**, 964-971. [Dept. Med., Sch. Dent., Univ. Rochester, N.Y.]
Modified globin prepared from human red cells by partial hydrolysis was given by vein to 4 subjects to supplement a low-protein diet. Metabolic studies were similar to those made previously with serum albumin (Abst. 2292, Vol. 19). Globin was estimated in plasma and urine.
Administration of 4 or 2 units globin daily caused nausea and vomiting and, after 8 days, refusal of food in 3 subjects. The fourth subject refused food after 3 days at 4 units daily, but ate all his diet for 10 days of 2 units daily, despite nausea. The results indicated that globin was readily metabolised and was efficiently converted to tissue protein until energy intake became inadequate.
One unit of globin contained 2.4 g. N.

GABUZDA, G. J. (Jr.), PHILLIPS, G. B. and DAVIDSON, C. S. **Nutritive adequacy and clinical tolerance of modified human globin.** *J. Clin. Invest.*, 1953, **32**, 899-908. [Thorndike Mem. Lab., Boston City Hosp., Mass.]

The average N content of samples of modified human globin was 15.7 per cent. Analysis for essential amino-acids showed a low content of isoleucine. When globin furnishing 9.6 g. N daily was injected intravenously for 8 and 11 days, respectively, into 2 subjects on a protein-free diet adequate in energy, bodyweight and N balance were maintained whether or not isoleucine was given by mouth. When an equivalent amount of food protein was subsequently given by mouth no change ensued. Administration of globin by vein to 3 men on constant diets containing protein caused N retention to increase. When globin was withdrawn after 5 or 6 days N retention decreased. Two of these men were then given by mouth protein supplements equivalent to the amount of globin, whereupon N retention increased as before. A sixth man given by vein an amino-acid mixture equivalent in N content to the globin previously given by vein showed a smaller positive N balance than with the globin.

Approximately 25 per cent. of infused globin was excreted in urine as protein. Significant qualities of globin were not detected in serum 24 hr. after globin administration, and the rise in plasma and urinary α -amino-N after infusion suggested rapid metabolism of globin. In clinical tolerance tests 20 subjects who received daily infusions of 16 or 32 g. globin for several days showed frequent occurrence of transient flushing, pruritus and mild pyrogenic reactions but no serious reaction.—F. C. Aitken.

MAGEE, D. F., KIM, K. S. and IVY, A. C. **Effect of dietary protein on the fat content of feces.** *Amer. J. Physiol.*, 1953, **175**, 310–312. [Dept. Clin. Sci., Chicago Professional Coll., Univ. Illinois.]

Purified diets were given to dogs and to rats. The dogs had 9 or 27 per cent. maize oil or none, and 2 levels of casein, the lower 14 or 20 and the higher 40 per cent.; the diets were changed over so that data were available for the same animals on low and high intakes of casein. The rats were in 2 groups on diets containing cellu flour 3.5, salt mixture 3.5 and maize oil 6 per cent., one of which contained 16 and 71 per cent. and the other 70 and 17 per cent. of casein and sucrose, respectively.

In both species the fat content of faeces was significantly lower with the high than with the low casein intake. The causes suggested are increases in output of cholate, or in production of pancreatic lipase, or both.—D. Harvey.

YULE, C. L., LUCAS, F. V., JONES, C. K., CHAPIN, S. J. and WHIPPLE, G. H. **Inflammation and protein metabolism studies of carbon-14-**

Vol. 24, No. 2

labeled proteins in dogs with sterile abscesses. *J. Exp. Med.*, 1953, **98**, 173–194. [Dept. Pathol., Sch. Med. Dent., Univ. Rochester, N.Y.]

After production of sterile abscesses by subcutaneous injection of turpentine, dogs were given ^{14}C -labelled plasma from a donor dog by vein or by mouth, or a mixture of amino-acids containing lysine- ϵ - ^{14}C by mouth. There was less absorption of ^{14}C from labelled protein given by mouth than in controls without abscesses, presumably because of impaired digestion. Turnover of albumin and fibrinogen was considerably increased, though globulin turnover was normal. Elimination of ^{14}C as CO_2 was increased, particularly during the period of high fever and accelerated albumin turnover, before localisation of the abscesses and decline in fibrinogen concentration. In dogs given ^{14}C by mouth there was also increased $^{14}\text{CO}_2$ elimination during absorption. Urinary excretion of ^{14}C was unaltered.

The appearance of ^{14}C in new red blood cells was much reduced, particularly when the ^{14}C was injected. The pus from the sterile abscesses contained roughly as much ^{14}C activity as the liver. The supernatant fluid had an activity proportional to that of the plasma, i.e., greater when the ^{14}C was given intravenously; the activity of the pus cells was the same whatever the source of ^{14}C . There was a reduction in labelling of skin, hair and skeletal muscle compared with controls, and relatively greater activity of liver and kidney.

SILICIANO, A. M. and NASSET, E. S. **Nitrogen balance and growth of the rat as affected by certain fruits in the diet.** *J. Nutrition*, 1953, **51**, 403–411. [Dept. Physiol., Sch. Med. Dent., Univ. Rochester, N.Y.]

Groups of 5 and 6 adult rats were given diets containing 2.5 and 5 per cent. protein, respectively, derived equally from casein and dried banana. In the diets of control pair-fed rats all the protein was in the form of casein; cellulose flour and banana ash were included to make the diets resemble the experimental diets in non-protein components. Similar inclusions were made in protein-free diets given to groups of 10 and 12 rats. With both 2.5 and 5 per cent. protein, N balance was the same for casein and casein plus banana diets, but utilisation of absorbed N was

higher in rats given banana as source of half of the N intake. In further trials neither the water-soluble nor the water-insoluble fraction of banana influenced N balance in adult rats given diets in which casein was the source of protein.

Addition of banana fractions or inclusion of 9 per cent. fresh fruit pulp solids from banana, pineapple or apple in diets containing 10 per cent. protein from casein did not affect the rate of growth of weanling rats fed to appetite.

FISCHER, M. A. and GARRITY, G. C. **Protein metabolism in the choline-deficient rat. 1. Effect of choline on serum proteins.** *J. Biol. Chem.*, 1953, **204**, 759-767. [Dept. Physiol. Chem., Sch. Med., Univ. Pittsburgh, Pa.]

Rats fed on a basal diet containing 18 per cent. casein, with fat, sucrose, salts and vitamins, developed fatty livers after 3 days and haemorrhagic enlargement of the kidneys after 6 days. Addition of 2 mg. choline daily reduced kidney damage, but had little effect on the liver lipid content; increasing the choline to 6 mg. daily reduced the liver lipid almost to normal. Serum proteins were estimated electrophoretically. In all the experimental animals the albumin was lower during the first 5 days than in controls on a stock diet; after a transient rise there was another fall for a few days in animals on the basal diet only; it is suggested that this was associated with the kidney damage. The α -globulins and possibly the β_1 -globulins, and also the phospholipin content, were increased after about the 8th day in rats on the basal diet. The β_2 -globulins were slightly higher in rats given choline than in those on normal or basal diets. γ -Globulins showed a slight increase in animals given choline after 6 days on the basal diet.—C. Warner.

HELLER, H. and BLACKMORE, K. E. **Absence of correlation between fatty changes in the liver and impairment of water diuresis in protein-deficient mice.** *Brit. J. Nutrition*, 1953, **7**, 349-356. [Dept. Pharmacol., Univ. Bristol.]

Adult male mice received a stock diet for 4 weeks before experimental diets were given. The experimental control diet, SF, contained, per cent., casein 18, wheat starch 63, groundnut oil 12, cod liver oil 3, salt mixture 4, with B vitamins and tocopherol. Diet BB had the same fat content, but was deficient in protein and choline, containing only 0.5 per cent. casein. Diet BC was like diet BB, but with choline added at 50 mg. per 100 g. Diet TT contained, per cent., minced turnips 81.5, wheat starch 7.0, groundnut oil 3.5, cod liver oil 4, salt mixture 4, and B vitamins; it was low in

energy and protein, but contained 75.6 mg. choline per 100 g. All were given to appetite.

All the protein-deficient diets produced loss of appetite and weight, and plasma protein levels fell. Fat accumulated rapidly in the livers of mice on diet BB and there was a transient increase on diets BC and TT, not statistically significant after 9 days. The diuretic response to administration of water was greatly decreased in animals on diet BB after 7 days, when fatty changes were greatest, and even more impaired after 10 days, though fatty changes were then less pronounced. There was some decrease in diuretic response on diets BC and TT; thus response was not related to degree of fatty change.—D. Duncan.

BENDER, A. E., MILLER, D. S., TUNNAH, E. J. and BLACK, W. A. P. **Biological value of algal proteins.** *Chem. and Indust.*, 1953, No. 50, 1340-1341. [Crookes Laboratories, Ltd., Park Royal, London.]

Samples of *Rhodymenia palmata*, *Laminaria cloustoni*, *Ascophyllum nodosum* and *Pelvetia canaliculata* were dried at 40° to 60° C. for 6 to 8 hr. and milled to pass a 64-mesh screen. The dried milled seaweeds contained, in the above order, 23.5, 6.4, 8.8 and 12.7 per cent. protein.

Net protein utilisation (NPU) by rats was estimated by the method of Bender and Miller (Title 2726, Vol. 23). Difficulty was experienced in inducing the animals to eat some of the samples, and several treatments designed to increase palatability are described. *R. palmata* appeared to be the only useful source of protein and had an NPU of 42. It may find a use as a feed for animals if the mechanical difficulties of collecting it separately can be overcome.—P. C. Jowsey.

2039

MONDER, C. and RAMSTAD, P. E. **The effect of ball-milling upon certain properties of proteins.** *Arch. Biochem. Biophys.*, 1953, **46**, 376-384. [Sch. Nutrit., Cornell Univ., Ithaca, N.Y.]

During ball-milling of egg albumin, solubility was lowest and titratable sulphydryl groups were highest after about 600 hr.; solubility rose slowly up to about 1800 hr. and then more rapidly. There was no change in the content of methionine, tyrosine or phenylalanine, and only slight changes in histidine and tryptophan as estimated microbiologically, but cystine decreased from 2.9 to 2.7 g. per 16 g. N. Formol titration showed an increase of 1.0×10^{17} carboxyl groups per mg. Digestibility by trypsin increased steadily through the whole period of milling and at the end of 2160 hr. was greater than that of heat-denatured uncoagulated albumin. These findings are thought

N.A. and R., April 1954

to show denaturation with oxidation and breaking of secondary linkages, together with some slight degradation, during the first 600 hr. of ball-milling, followed by more extensive splitting of primary bonds, formation of small soluble peptides and increased susceptibility to proteolytic attack.

When wool was treated similarly, solubility and titratable sulphhydryl groups increased throughout the 2064 hours' milling; all the amino-acids tested decreased in concentration after the first 800 hr. to about 60 or 70 per cent. of their initial values, except tryptophan, which decreased from 0.55 to 0.12 g. per 16 g. N. This destruction of amino-acids is attributed to the long, exposed wool keratin molecule, as compared with the close, compact albumin molecule. Formol titration showed an increase of 1.8×10^{17} carboxyl groups per mg. Digestibility by trypsin increased rapidly for the first 900 hr. of milling and thereafter very slowly.—C. Warner.

2040

DAS, D. P., MURTHY, H. B. N. and SWAMINATHAN, M. **Studies on the nutritive impairment of proteins heated with carbohydrates. 1. *In vitro* digestion studies.** *Bull. Central Food Technol. Res. Inst. Mysore*, 1953, **2**, 259–261.

Casein was autoclaved for 2 hr. at 15 lb. per sq. in. with glucose, sucrose, lactose or maltose with or without water or starch, before digestion *in vitro* by trypsin or pepsin. Digestion was slower after heating with sugars than under the other conditions investigated. With small amounts of glucose or lactose and different autoclaving conditions, 5 lb. per sq. in. for 30 min., no reduction in the rate of digestion was found.

The rates of digestion of the proteins of "khawa" prepared from skimmed milk powder or buffalo milk and cane sugar were only slightly lower than those for the original milk powder and milk.

HUISMAN, T. H. J. Enkele beschouwingen aangaande het bepalen der afzonderlijke aminozuren in het bloed. [Some observations on the estimation of single amino-acids in blood.] *Nederland. Tijdschr. Geneesk.*, 1953, **97**, 2732–2743. [Kinderclin., Acad. Ziekenhuis, Groningen.]

Methods of estimating amino-acids in blood are reviewed. The method preferred is that of Moore and Stein (Abst. 4469, Vol. 21), a chromatographic method with Dowex 50. Clinical studies of the levels of 22 amino-acids in the ultrafiltrate of plasma in 2 normal men, 1 control and 2 infants with scurvy and 1 control and an infant with refractory rickets are discussed. The loss of the amino-acids histidine, serine, glycine, lysine and threonine in rickets is caused by failure of renal tubular reabsorption; the level in blood is not raised. (See Abst. 2280, Vol. 23.)—I. Leitch.

2044

ALMQUIST, H. J. **Principles of amino acid balance.** *Arch. Biochem. Biophys.*, 1953, **46**, 250–251. [Grange Co., Modesto, Calif.]

When a dietary protein is partly deficient in one essential amino-acid, the fraction which contains amino-acids in optimum proportions to the deficient amino-acid is the only part available for growth. Increasing the amount of the unbalanced protein will increase the amount of the balanced fraction and hence permit increased growth up to the natural limit of growth rate. Increasing the relative amount of the deficient amino-acid increases the proportion of the protein available for growth until the whole of the protein is so used or the natural limit is reached. If a slightly deficient protein is given at a high level so that maximum growth response is obtained, addition of the deficient amino-acid will increase the efficiency of utilisation of the feed.

The author illustrates these principles with previously published results.—C. Warner.

2045

WOMACK, M., MARSHALL, M. W. and PARKS, A. B. **Some factors affecting nitrogen balance in the adult rat.** *J. Nutrition*, 1953, **51**, 117-130. [Bur. Human Nutrit., Agric. Res. Admin., U.S. Dept. Agric., Washington, D.C.]

Diets containing the non-essential amino-acids at concentrations of 0.1 and the essential amino-acids at 0.1 or 0.2 per cent., ammonium citrate, carbohydrate, fats, salts and vitamins were given to male rats, with or without a previous period of 18 days on a similar but N-free diet. With sucrose as carbohydrate, increasing the average daily N intake of undepleted animals from 35.8 to 46.4 or 72.6 mg. by the addition of ammonium citrate caused small, statistically non-significant increases in the N balance from -23.2 to -19.4 or -17.2 mg. When the essential amino-acids were given at the higher level, providing a N intake of 47.7 mg., the N balance was significantly improved to -7.2 mg. In depleted rats N losses were less, but otherwise the results were similar.

When maize dextrin was substituted for sucrose, the rats were approximately in N equilibrium, and there was little or no effect of ammonium citrate, extra essential amino-acids or earlier depletion. Addition of 1 per cent. sulphasuccidine further improved N balance. Potato dextrin had a much smaller effect, not significant at the higher intake of essential amino-acids.—C. Warner.

PEREIRA, M. D., CONRAD, E. J., and ELMAN, R. **The influence of inanition on the utilization of a low caloric-amino acid mixture given intravenously.** *Surgery*, 1953, **34**, 874-879. [Div. Surg. Metabol., Homer G. Phillips Hosp., St. Louis, Mo.]

A positive N balance was maintained in 13 extremely undernourished patients during intravenous administration for 3 days of an amino-acid and glucose mixture, providing a daily intake of 12.6 g. N and 400 to 800 non-protein Cal. The patients had lost on an average 65 per cent. of their normal weight and had been in negative N balance because of the anorexia of disease or mechanical inability to eat. The urinary N excretion during the days of infusion was similar in all the patients and in some was less than the output during the days preceding the infusion, when they were maintained on glucose alone. There was no correlation between N retention and weight loss, and no difference in N retention between patients receiving 400 and those receiving 800 Cal. from carbohydrate. Three of the patients were brought into a state of repletion by a good diet and the

amino-acid infusion was repeated; N retention was much less than before repletion and was negative in 2 of the 3 patients. It is concluded that the N balance on a low energy intake is related to the body protein stores and is a measure of the degree of protein depletion.—L. Wills.

PRICE, W. A. (Jr.), TAYLOR, M. W. and RUSSELL, W. C. **The retention of essential amino acids by the growing chick.** *J. Nutrition*, 1953, **51**, 413-422. [Dept. Agric. Biochem., New Jersey Agric. Exp. Stat., New Brunswick.]

Chicks were fed from 1 week of age on a mixture of soya bean meal 20, dried distiller's solubles 4, dried whey 4, fishmeal 4, meat scrap 3, alfalfa meal 3, minerals, vitamins and cereals and cereal offals to 100. After they had gained 160 g. they were slaughtered and the carcass contents of N and essential amino-acids were estimated and compared with those of similar birds killed at 1 week old.

It was estimated that 33 per cent. of the N in the feed had been retained. For individual amino-acids the retentions varied from 27 per cent. for tryptophan to 43 per cent. for lysine, although the lysine content of the ration was above the U.S. recommended allowance and that of tryptophan slightly below it. Of the essential amino-acid intake not recovered in the carcass less than one-third was found in the excreta.

Parallel trials were made with another ration containing only 16.5 per cent. crude protein, but with all the supplementary protein coming from animal by-products. With this ration 56 per cent. of the N was retained in the carcasses, with from

39 to 71 per cent. retention of individual amino-acids.

There was no significant difference between the amino-acid composition of the chicks receiving the different rations, although the second contained only 68 per cent. of the recommended allowance of arginine, and the first was deficient in methionine and tryptophan.—K. J. Carpenter.

2050

CRAMPTON, R. F. and SMYTH, D. H. **The excretion of the enantiomorphs of amino-acids.** *J. Physiol.*, 1953, **122**, 1-10. [Dept. Physiol., Univ. Sheffield.]

When racemic mixtures of alanine, histidine and methionine were injected intravenously into cats it was found that the D:L ratio was less than unity in the plasma, but more than unity in the urine. Clearance studies with alanine and methionine, using creatinine clearance to estimate glomerular filtration rate, showed that the L-isomers were actively reabsorbed by the tubules, with plasma threshold values of about 0.5 mg. per ml. for L-alanine and 1.3 mg. per ml. for L-methionine. With the D-isomers slight reabsorption occurred, presumably passive, and no threshold value was noted. The diffusion rates of D- and L-alanine were the same through cellophane or through rat intestine kept at 10° C. to abolish the mechanism for active transfer of L-amino-acids.

It is concluded that the reduced nutritional value of D-amino-acids is influenced by the failure of the kidney to retain them.—C. Warner.

2051

ESH, G. C. and SOM, J. M. **Nutritional survey of available food materials. 4. Availability of methionine, cystine and tryptophan in pulses.** *Indian J. Physiol. Allied Sci.*, 1953, **7**, 158-162. [Bengal Immunity Res. Inst., Calcutta.]

Bengal, green and black gram were relatively good and Khesari was a poor source of methionine; Bengal and black gram and Khesari were good and lentil was a poor source of cystine; all the pulses were good sources of tryptophan. The availability of methionine for rats was low in lentil and Khesari; that of cystine was low in red gram, dried peas and Khesari; that of tryptophan was low in red gram.—C. Warner.

HARTSOOK, E. W. and JOHNSON, B. C. **Effects of dietary terramycin and methionine supplements on fat and protein gains in weanling rats.** *J. Nutrition*, 1953, **51**, 205-218. [Div. Animal Nutrit., Univ. Illinois, Urbana.]

Weanling rats were fed on diets containing a modified soya bean protein, in which cystine and methionine together formed 0.42 per cent. of the

diet, and the effects were studied of adding methionine, terramycin or both.

No significant effect was found when the methionine was increased to give a cystine plus methionine content of 0.81 per cent. Addition of terramycin resulted in slight increases in feed intake, carcass dry matter and feed efficiency, a marked increase in carcass ether extract and a slight decrease in N efficiency. The interaction of methionine and terramycin increased carcass N and N efficiency and decreased carcass ether extract. Thus when the diet was low in methionine the increase in weight due to terramycin was mainly ether extract, but when methionine was adequate the increase was mainly protein.

MACHLIN, L. J., PEARSON, P. B., DENTON, C. A. and BIRD, H. R. **The utilization of sulfate sulfur by the laying hen and its incorporation into cystine.** *J. Biol. Chem.*, 1953, **205**, 213-219. [Bur. Animal Indust., U.S. Dept. Agric., Beltsville, Md.]

Laying hens were given ³⁵S as sulphate by mouth or vein. Radio-active S was found in the white and yolk of the eggs laid, the peak concentrations occurring 3 or 4 days after administration. The method of administration made little difference to the quantities present in the eggs. About 35 per cent. of the ³⁵S in the eggs was non-sulphate or "organic" S; a higher proportion of this was in the white than in the yolk. Cystine was labelled, but not methionine.—R. Hill.

JACKSON, H. D., MERTZ, E. T. and BEESON, W. M. **Quantitative valine requirement of the weanling pig.** *J. Nutrition*, 1953, **51**, 109-116. [Dept. Agric. Chem., Purdue Univ., Lafayette, Ind.]

Weanling pigs received diets of equal crude protein content, 12.8 per cent., based on maize with supplements of crystalline essential amino-acids and ammonium citrate, minerals, liver extract and cerelese. The amounts of the amino-acids given were such as to bring the total available up to the minimum required for good growth where this was known, or were based on experience with rats. It was assumed that the digestibility of the constituent amino-acids was the same as that of the maize protein and that the D-isomers of lysine, threonine and valine were physiologically inactive and those of phenylalanine, methionine and tryptophan active.

Weight gain, feed consumption and feed efficiency were all lower when the available L-valine content of the diet was 0.3 than when it was 0.4, 0.5, 0.6 or 0.7 per cent., these 4 levels giving similar results. It is concluded that the L-valine requirement of the weanling pig is 0.4 per cent.

of the diet or 3.6 per cent. of the digestible crude protein.—C. Warner.

LANG, K. and OSTER, H. Untersuchungen über den Stoffwechsel der γ -Aminobuttersäure und der α -Aminoisobuttersäure. [Metabolism of γ -aminobutyric acid and α -aminoisobutyric acid.] *Biochem. Ztschr.*, 1953, **324**, 443–446. [Physiol. Chem. Inst., Johannes Gutenberg Univ., Mainz.]

γ -Aminobutyric acid and α -aminoisobutyric acid given to young rats in amounts of 50 mg. per head daily did not change the rate of growth in a 3 weeks' test. With intraperitoneal injection the lethal dose for the mouse was about 10 mg. of γ -aminobutyric acid per g. bodyweight and slightly more of α -aminoisobutyric acid. Homogenates of liver, kidney and brain oxidised both amino-acids to a small extent, but muscle tissue was ineffective. After injection of 100 to 500 mg., rats excreted both acids quantitatively in the urine, and at the same time excretion of other amino-acids increased considerably, as shown by paper chromatography.

SCHÜLTZ, G. O. Geht die L-Glutaminsäure im Tierkörper über die L-Pyrrolidonecarbonsäure in L-Prolin über? [Is L-glutamic acid in the animal body converted to L-proline by way of L-pyrrolidone carboxylic acid?] *Biochem. Ztschr.*, 1953, **324**, 295–300. [Diagnost. Inst., Freiburg i. Br.]

No proof has been given of the textbook assertion that proline is formed in the animal body from glutamic acid, with pyrrolidone carboxylic acid as an intermediate product. All attempts by the author to reduce this amino-acid to proline *in vitro*, whether by chemical or biological means, resulted in failure. Its behaviour in metabolism was investigated by means of experiments on rabbits. In feeding tests only 2 per cent. of the ingested pyrrolidone carboxylic acid was recovered from the urine, but after parenteral administration 92 to 94 per cent. was excreted. The explanation given of this difference in retention is that L-pyrrolidone carboxylic acid given by mouth is hydrolysed in the pH range of the gastric juice to L-glutamic acid, any unhydrolysed excess being excreted through the bile. A large part of the glutamic acid formed from the amino-acid is utilised in intermediary metabolism, but proline formation does not take place. This was shown by the injection experiments, in which the pyrrolidone carboxylic acid was excreted through the urine as a foreign body. L-Pyrrolidone carboxylic acid resists biological reduction systems in the body just as completely as it does all attempts at reduction *in vitro*.—M. B. Richards.

NASSET, E. S. and ELY, M. T. Nitrogen balance of adult rats fed amino acid diets low in L-, DL- and D-tryptophan. *J. Nutrition*, 1953, **51**, 449–461. [Dept. Physiol., Sch. Med. Dent., Univ. Rochester, N.Y.]

The technique and experimental diets were similar to those described by Nasset *et al.* (Abst. 5099, Vol. 21), except that tryptophan instead of threonine intake was reduced. The natural isomer was given to 35 rats, DL-tryptophan to 30 and D-tryptophan to 26.

The requirement for maintenance of N equilibrium in the adult rat was estimated, in mg. per kg.^{0.75} bodyweight daily, as L-tryptophan 4.4 ± 0.22 , DL-tryptophan 6.0 ± 0.31 , or D-tryptophan 8.8 ± 0.57 .—D. Duncan.

LANG, K. and BITZ, H. Über den Stoffwechsel der ϵ -Aminocaproinsäure. [Metabolism of ϵ -aminocaproic acid.] *Biochem. Ztschr.*, 1953, **324**, 495–498. [Physiol. Chem. Inst., Johannes Gutenberg Univ., Mainz.]

ϵ -Aminocaproic acid does not act as an antagonist to metabolism in rats. Its toxicity is slight, the lethal dose by intraperitoneal injection being about 2 g. for animals weighing from 140 to 170 g. A daily intake of 100 mg. for 7 weeks did not affect the growth of young rats. Homogenates of liver and kidney oxidised the acid to some extent; the enzyme involved is very unstable and is not contained in the cyclophorase system, and the oxidation is not a deamination. After injection of 500 mg. into rats, most of the acid was excreted unchanged in the urine, and at the same time the excretion of other amino-acids increased.

KLINC, L. Über die "scheinbare" und "wahre" Ausnutzung des Fettes der Cerealien und Leguminosen. ["Apparent" and "true" utilisation of the fat of cereals and legumes.] *Biochem. Ztschr.*, 1953, **324**, 385-396. [Inst. Ernährungsforsch., Serb. Akad. Wissensch., Belgrade.]

Values for "apparent" utilisation of the fat of cereals and legumes quoted in the literature and in the tables of König and Schall are considered misleading because of the different experimental methods and failure to take account of metabolic faecal fat. "True" utilisation as a percentage is defined as

$$\frac{NF - (KF - SF)}{NF} \times 100,$$

where NF is fat intake, KF total faecal fat and SF metabolic faecal fat. This is not to be confused with "true" digestibility, since the total faecal fat may include fat of dietary origin which has been digested but not absorbed. It is not feasible to correct for metabolic faecal fat by a single numerical factor for cereals differing in grain size and crude fibre content.

Six men and 3 women in good health, aged from 27 to 48 years, were subjects of 25 experiments. They had cereal or legume as sole food, apart from tea with sugar, for from 3 to 6 days, followed immediately by 3 to 5 days of the cereal or legume defatted with ether. This allowed estimation of SF. Maize was taken as polenta, millet (proso) as gruel, peasemeal, beanmeal and oat flakes as purée, and the others as bread. All except oat flakes and soya bean meal were tested on 2 subjects.

From the tabulated results it is clear that the values for "apparent" utilisation may be low or erratic and vary with the solvent used to extract the faeces, but the values for "true" utilisation are consistent and high, irrespective of the fat and crude fibre contents of the cereal or legume. The

mean "true" utilisation and "true" digestibility were as follows: wheat flour, 90 per cent. extraction, 90, 97; 70 per cent. extraction, 95, 96; rye flour, 75 per cent. extraction, 71, 88; barley meal 82, 86; oatmeal 92, 97; oat flakes 85, 93; maize meal 88, 93; millet (proso) 81, 95; buckwheat meal 79, 85; beanmeal 82, 91; lentil meal 82, 86; peasemeal 85, 88; soya bean meal 91, 95.

WADDELL, W. R., VAN ITALLIE, T. B., GEYER, R. P. and STARE, F. J. **Liver function during intravenous infusion of emulsified fat to humans.** *Ann. Surg.*, 1953, **138**, 734-740. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

Emulsions were prepared from 15 per cent. coconut or olive oil with 1 per cent. soya bean phosphatide and 1 per cent. polyglycerol ester of oleic acid as emulsifying agents. The 21 patients were all semi-starved and unable to eat, and 8 of them had major operations during the period of fat infusion. They received 500 or 1000 ml. infusions at a time.

Bromosulphalein retention and cephalin flocculation tests showed no change attributable to fat administration, but indicated the effects of the diseases or of surgery and anaesthesia. No consistent change was observed in serum alkaline phosphatase, serum protein, bilirubin, cholesterol and cholesterol esters, or prothrombin time. It is concluded that fat administration had no adverse effect on liver function.—D. Duncan.

MENG, H. C. and YOUNG, J. B. (with CAIN, W. B. and GRIMES, D. M.) **The indispensability of fat in parenteral alimentation in dogs.** *J. Clin. Nutrit.*, 1953, **1**, 372-383. [Dept. Physiol., Sch. Med., Vanderbilt Univ., Nashville, Tenn.] Spanish summary.

With a technique and diet previously described (Abst. 783, Vol. 20) one dog was maintained for 4 weeks on complete parenteral feeding, receiving 80 Cal. per kg. bodyweight daily, of which 34 per cent. came from fat, 16 from protein and 50 from carbohydrate. It remained healthy and lively and gained 7.6 per cent. of its initial weight. Two other dogs were given the same treatment except that the fat was replaced by an isocaloric amount of glucose and in addition 100 mg. methyl linoleate, 100 mg. methyl linolenate and 10 mg. methyl arachidonate were given daily per kg. bodyweight. They lost 9.2 and 4.3 per cent. of their initial weight, were not alert and lacked a sense of well-being. Two dogs had the fat replaced by glucose, but did not receive fatty acids. They lost 9.1

and 6.2 per cent. of their initial weight, appeared emaciated and apathetic and developed lesions considered characteristic of essential fatty acid deficiency.

Laboratory tests made during the trial and a histological examination after death did not reveal any abnormality attributed to the feeding.

WADDELL, W. R., GEYER, R. P., CLARKE, E. and STARE, F. J. **Role of various organs in the removal of emulsified fat from the blood stream.** *Amer. J. Physiol.*, 1953, **175**, 299-302. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

The effects of evisceration and of removal of the liver, spleen, kidney, intestine or adrenals on the clearance of fat from the blood were studied in rats. An emulsion containing 25 per cent. coconut oil and 3 per cent. cerebroside was given intravenously.

Evisceration impaired fat clearance so that in the first hour after injection only 15 per cent. of the fat was removed from the blood, compared with 61 per cent. in normal rats. When two-thirds of the liver was removed fat clearance in the first hour was 35 per cent., but there was a considerable accumulation of fat in the remaining liver tissue, and this was thought to indicate that the remaining tissue was compensating by removing more fat than the corresponding amount of tissue did normally. When fat emulsion was given 1 hr. after removal of the spleen, 43 per cent. was cleared in the first hour, but by the following day clearance was normal. Removal of the kidneys did not affect fat clearance until the animals had become uraemic; the effect might then be a secondary one involving the liver. Removal of the intestine from the pylorus to the lower rectum only slightly delayed fat clearance, probably because of reduced portal blood flow. Adrenal removal was without significant effect. The liver and spleen are thus considered to exert the greatest influence on the rate of fat clearance.—D. Duncan.

FAVARGAR, P. and GERLACH, J. **Variations dans le mode de résorption des différentes graisses et acides gras chez le rat. [Variations in method of absorption of different fats and fatty acids by the rat.]** *Helv. physiol. pharm. Acta*, 1953, **11**, 239-250. [Inst. Chim. Physiol., Univ. Geneva.]

Mixtures of fats and fatty acids were given to fasting rats: the free acids included elaidic acid and palmitic, stearic and oleic acids labelled with deuterium; some of the labelled acids were also incorporated individually into triglycerides. Three hours after receiving the lipid mixture the animals

were killed and the intestines were removed and cut into 3 portions. Free fatty acids, glyceride and phospholipin fatty acids were separately isolated from each portion and their deuterium content was estimated.

The partition of labelled fatty acids between the different lipid classes varied not only with the nature of the fatty acid, but more with the composition of the mixture. The differences were less in the composition of the phospholipins than in the glycerides.—G. A. Garton.

BOSE, S. M. and SUBRAHMANYAN, V. **Influence of dietary fats on the fatty acids composition of body-fat of albino-rats.** *Ann. Biochem. Exp. Med.*, 1951, **11**, 207-218. [Central Food Technol. Res. Inst., Mysore.]

Weanling albino rats were fed for 4 weeks on an almost fat-free diet composed of maize starch 65, extracted casein 15, sucrose 10, yeast 5 and salt mixture 5 per cent. The 64 litters were then equally divided into 4 groups; the first group were fed on the above fat-free diet for another 12 weeks. The other three groups were fed for 12 weeks on a diet containing maize starch 20, extracted casein 30, fat 30, sucrose 10, yeast 5 and salt mixture 5 per cent.; the fat consisted of cow ghee, refined groundnut oil or vanaspati (m.p. 37°C.) prepared from the groundnut oil. All diets were supplemented with vitamins A, D and E. Total body fat (excluding liver and alimentary tract) was then extracted from the minced carcasses with ethanol and ether and the combined fats from the animals of each group were analysed for component fatty acids by standard ester-fractionation technique.

The major component acids of the fat of rats on fat-free diet were oleic, palmitic and hexadecenoic acids, with smaller amounts of stearic, myristic and linoleic and traces of arachidic and arachidonic acids. The feeding of groundnut oil substantially raised the content of linoleic acid in the body fat and slightly increased the arachidonic acid content. The hexadecenoic acid content of the fat of all fat-supplemented groups was lower than that of the fat-free group. *iso*Oleic acid was identified in the fat of the group given vanaspati. The amounts of the saturated acids myristic, palmitic, stearic and arachidic were of the same order in the fat of all 4 groups. Lauric acid was found only in the fat of the group fed on cow ghee.—G. A. Garton.

BOSE, S. M. and SUBRAHMANYAN, V. **Effect of a high-fat rice diet on the deposition and fatty acids composition of liver-fat of albino-rats.** *Ann. Biochem. Exp. Med.*, 1952, **12**, 93-102. [Central Food Technol. Res. Inst., Mysore.]

N.A. and R., April 1954

About 1000 weanling albino rats were fed for 4 weeks on a poor South Indian diet and then for a further 4 weeks on the same diet supplemented with 30 per cent. cow ghee. The livers were then removed and the fat was extracted. The component fatty acids of the liver fat and the ghee were estimated by the ester fractionation technique.

Although the ghee contained about 20 per cent. of lower fatty acids, from butyric to capric, these were not deposited in the liver fat of the rats. The major component acids of the liver fat were palmitic and oleic acids; smaller amounts of myristic, stearic, hexadecenoic, linoleic and arachidonic acid were found, together with traces of lauric, arachidic and tetradecenoic acid.—G. A. Garton.

KAUNITZ, H. Studien über die Ernährung von Ratten mit hochoxydierten Fetten. [**Feeding rats with highly oxidised fats.**] *Arch. exp. Pathol. Pharmacol.*, 1953, **220**, 16-25. [Dept. Pathol., Columbia Univ., New York.]

Addition of highly oxidised lard to the diet of rats caused only mild changes if the animals were given all the known vitamins as separate suspensions. The severe disturbances reported by many workers from the use of highly oxidised fats may have been due to secondary deficiency diseases caused by rapid destruction of the vitamins of the diet by the oxidised fat. In rats on a complete diet the one constant change observed on addition of oxidised fat was a diminution in weight. This was not due to lack of unsaturated fatty acids or to decreased food intake, and probably not to disturbance of fat absorption. The weight loss, which was roughly parallel to the degree of oxidation of the fat, could be reduced by increasing the protein content of the diet. This indicates that the active components of the oxidised fat could be reduced and thereby inactivated by protein. The weight-reducing effect of highly oxidised fats was more pronounced when they were added to a diet deficient in protein or riboflavin, and the deficiency in these circumstances was much more severe with oxidised than with fresh fat.—M. B. Richards.

FINK, H. and SCHLIE, I. Eine neue Diät zur Erzeugung der alimentären Lebernekrose der Ratte (Champignon-Diät). [**A new diet for the production of alimentary liver necrosis in**

the rat. Mushroom diet.] *Naturwissenschaft-en*, 1953, **40**, 491. [Inst. Gärungswissenschaft, Univ. Cologne.]

The diet for production of liver necrosis in the rat consisted of mushrooms 25.6, wheat starch 62.7, liver oil 3.4, brewer's yeast 2, McCollum's or other salt mixture 4 and Ca phosphate 2.5 parts. Synthetic B vitamins may be used instead of the yeast. Cultivated mushrooms are cooked for 1 hr. with 100 ml. water to 9 kg. mushrooms and then minced. The other ingredients are added and the mixture is baked into biscuits in a drying oven at 70° C. This diet produced fatal liver necrosis in from 20 to 40 days in 95 per cent. of rats and was more reliable than the yeast diet previously used.

RUBINO, F. and SCAVO, R. Modificazioni istologiche delle isole di Langerhans nei ratti albini alimentati con dieta steatogena. [**Histological changes in the islets of Langerhans in albino rats given a diet to produce fatty liver.**] *Arch. Fisiol.*, 1953, **53**, 74-83. [Ist. Fisiol., Univ. Palermo.]

Histological examination was made of the pancreas of groups of 4 rats fed for 10, 15, 20 or 25 days on a diet containing, per cent., sucrose 48, fat 40, casein 5, agar 2 and salts 5, with adequate vitamins. Comparison was made with rats on a normal diet. As the period on the diet increased, the cells in the islet tissue lost their arrangement in rows, and there was atrophy and disappearance of basophil cells. After 25 days the islets were shrunken, with atrophy of almost all their cells.

THOMASSON, H. J. **Biological standardization of essential fatty acids (a new method).** *Internat. Ztschr. Vitaminforsch.*, 1953, **25**, 62-82. [Unilever Res. Lab., Zwijndrecht, The Netherlands.] German and French summaries.

Male albino rats were used in groups of 12, aged 21 days at the beginning of the experiment and weighing about 40 g. They were fed for 9 weeks on a diet with or without hardened coconut oil, but containing no essential fatty acid, and were given free access to water for 2 weeks. For the last 7 weeks the animals were caged individually and the water intake was limited to 14 ml. daily.

The rats each received 0.2 ml. of fat or fatty acids or of a mixture of hardened coconut oil with fat or fatty acid for 5 days weekly from the sixth to the ninth week inclusive. The weight gain produced by 10 mg. linoleic acid was taken as the unit of biological activity. The potency of the test substance was calculated by the method of Irwin (*J. Roy. Statist. Soc. Suppl.*, 1937, 4, 1).

The results of a large number of assays showed that biological activity was correlated mainly with the conjugable diene content of the fatty acid as estimated spectrophotometrically. The most potent acid found was arachidonic acid, its potency being about one-third as great again as that of linoleic acid or that of $\Delta^{6,9,12}$ -octadecatrienoic acid (γ -linolenic acid) obtained from the seed fat of *Oenothera biennis*. A much smaller response was given by $\Delta^{10,13}$ -nonadecadienoic acid and $\Delta^{9,12,15}$ -octadecatrienoic acid (linolenic acid). It appears likely that arachidonic acid is the active form of essential fatty acid in the animal body.

BERNHARD, K. and GLOOR, U. Einige weitere, im Sinne des sogenannten Vitamine F wirk-same Fettsäuren. [Some other fatty acids with the effect of the so-called vitamin F.] *Helv. physiol. pharm. Acta*, 1953, 11, 323-328. [Physiol. Chem. Inst., Univ. Basle.]

In repetition of the work of Guggenheim and Jürgens (Abst. 370, Vol. 17), in which a diet free of essential fatty acids, given to rats during the last half of pregnancy and during lactation, resulted in high mortality rate and poor growth in the young, it was found that the addition of stearic, 19:10-dihydroxystearic or 9:1 diketostearic acid to the mother's diet improved the growth rate and life expectancy of the young. The possible conversion of these acids into linoleic acid is discussed.—W. Godden.

2078

ROKKONES, T. A dietary factor essential for hair growth in rats. *Internat. Ztschr. Vitaminforsch.*, 1953, 25, 86-98. [Biochem. Inst., Vet. Coll. Norway, Oslo.] German and French summaries.

The percentage composition of the fat-deficient basal diet was sucrose 63, petroleum-extracted dried codfish meal 25, petroleum-extracted dried brewer's yeast 5, NaCl 1, CaCO₃ 1, salt mixture 5. Albino rats received this diet with weekly doses of vitamins A and D dissolved in ethanol and vitamin K in water. Growth of hair after clipping was studied.

The syndrome of higher unsaturated fatty acid deficiency as described by Burr (*J. Biol. Chem.*, 1929, 83, 345) was seen, with scale formation on the legs after 3 or 4 weeks in winter; in summer

scale formation was slight. Addition of 0.12 to 0.2 g. linseed oil daily to the diet increased the rate of hair growth, and fatty acids prepared from linseed oil and given subcutaneously were also effective. Linolenic or linoleic acid given by mouth as the methyl ester was as effective as the oil; 30 mg. linoleic acid daily produced better hair growth than 24 mg. linseed oil.—D. Duncan.

RODRÍGUEZ, R. R., CATTÁNEO, P., HOUSSAY, B. A. and UNO, B. Unsaturated fatty acids and alloxan diabetes. *J. Nutrition*, 1953, 51, 441-448. [Inst. Biol. Med. Exp., Buenos Aires, Argentina.]

Groups of male rats were fed to appetite for 1 month on high-carbohydrate or high-fat diets. The latter contained the same percentage of coconut oil, lard, olive oil, maize oil, sunflower oil, linseed oil, oleic acid, a mixture of palmitic and stearic acids or a mixture of caprylic and capric acids. The animals then received an injection of alloxan intraperitoneally or intravenously; mortality was recorded for the following 10 days. The survivors were fasted for 7 hr. before blood sugar was estimated.

The toxic and diabetogenic effects of alloxan were prevented in rats which received a high-fat diet, the fat of which consisted primarily of saturated fatty acids; diets rich in unsaturated fatty acids did not protect.—G. A. Garton.

HOBSON, W., JORDAN, A. and ROSEMAN, C. Serum-cholesterol levels in elderly people living at home. *Lancet*, 1953, 265, 961-964. [Dept. Social Indust. Med., Univ. Sheffield.]

Samples of blood were obtained from 98 men aged from 66 to 85 years and from 141 women aged from 61 to 87 years; 36 men and 34 women students between 18 and 29 years of age were control subjects. Food consumption was recorded by 71 men and 84 women for a week.

The range of serum cholesterol values was for men 176 to 409 mg. and for women 200 to 481 mg. per 100 ml. In both sexes the means for the older subjects, men 268 and women 310, were greater than for the younger, men 211 and women 233 mg. per 100 ml. For both age groups the

N.A. and R., April 1954

mean was significantly higher in women than in men. Heavy drinkers, of whom there were 12 among the men, had, on the average, lower levels than had lifelong teetotallers. Correlation of serum cholesterol with intake of fat or with thickness of an abdominal skinfold was significant for women, but not for men. No correlation could be established between serum cholesterol and presence of conditions possibly associated with atherosclerosis, or between it and eye changes associated with ageing.—D. Harvey.

2082

THIELE, O. W. Die Acetalphosphatide des Blutserums bei alimentärer Lipämie. [The acetalphosphatides of blood serum during alimentary lipaemia.] *Ztschr. ges. exp. Med.*, 1953, **121**, 246-253. [Med. Klin., Justus-Liebig-Hochsch., Giessen.]

In healthy subjects after a meal of 50 ml. olive oil there was a significant increase in serum phosphatides and total lipids, but not in serum cholesterol. The average acetalphosphatide content remained unaltered, although there was a distinct decrease in some. This decrease was probably connected, not with the fat meal, but with the amount of blood withdrawn. The olive oil contained only very small amounts of acetalphosphatides.—M. B. Richards.

OLIVER, M. F. and BOYD, G. S. The plasma lipids in coronary artery disease. *Brit. Heart J.*, 1953, **15**, 387-392. [Dept. Cardiol., Royal Infirmary, Edinburgh.]

Plasma lipids were estimated in a group of 200 subjects for whom there was cardiographic evidence of coronary artery disease, and in a group of 200 in-patients who were similar in mean age and age distribution but without signs of artery disease. There were 149 men and 51 women in the artery disease group and data are presented for 5 decades of age from 30 years upwards.

Men, but not women, in the youngest age group with the disease showed a mean level above normal for total cholesterol. For both sexes those with the disease also gave mean values for total cholesterol and for its ratio to phospholipins which were significantly above the levels for the control group at all ages, with one exception; at 50 to 59 years the values for the 2 groups of women were similar

because of a rise which occurred in each value at that time in women in the control group. The elevation, however, was true only for the age groups as such; individual values within them overlapped on occasion.

The possible existence of a hormonal basis for the rise in plasma lipids in the control group in the sixth decade is discussed.—D. Harvey.

FRIEDMAN, M., BYERS, S. O. and SHIBATA, E. Observations concerning the production and excretion of cholesterol in mammals. 10. Factors affecting the absorption and fate of ingested cholesterol. *J. Exp. Med.*, 1953, **98**, 107-117. [Harold Brunn Inst., Mount Zion Hosp., San Francisco, Calif.]

The intestinal absorption of cholesterol was studied in groups of male rats, some of which had cannulae to divert bile from the intestine. Cholesterol was given by mouth, with and without Na cholate. Faeces were collected for 72 hr., after which the animals were killed. The faeces and intestinal contents were analysed for total sterols, cholesterol and "non-cholesterol sterols".

In a similar experiments intestinal lymph was collected from the abdominal portion of the thoracic duct and its cholesterol content was estimated; in some experiments cholesterol was estimated also in blood, liver and other tissues.

Analysis of faeces indicated greater absorption of cholesterol than did lymph analysis; the two methods of estimation agreed within about 20 per cent. In the intact rat the extent of cholesterol absorption is inversely proportional to the intake; faeces analysis showed that about 47 per cent. of a 50 mg. dose was absorbed, but only about 34 per cent. of a 100 mg. dose. The absorbed cholesterol was found mainly in the liver. Though bile is necessary for normal absorption of cholesterol, small amounts were found to be absorbed in its absence. Excess cholate intake increased the absorption of cholesterol by normal rats. The studies indicated that about 14 mg. cholesterol is daily excreted into the intestine of the rat and that part of it is re-absorbed.—G. A. Garton.

BOYD, G. S. The possible role of coenzyme A in the biosynthesis of cholesterol in the rat. *Biochem. J.*, 1953, **55**, 892-895. [Dept. Biochem., Univ. Edinburgh.]

Two groups of rats were fed for 40 days on a diet containing 10.5 per cent. of neutral fat (olive oil), with or without Ca pantothenate; 2 other groups were fed for the same time on an isocaloric fat-deficient diet, with or without pantothenate. At the end of the experiment the animals were anaesthetised and bled from the carotid artery.

Total and free cholesterol were estimated in plasma and liver. Co-enzyme A was estimated in aqueous extracts of liver.

The concentrations of ester cholesterol in liver and plasma appeared to depend on dietary pantothenate, and hence on the content of co-enzyme A in the tissues, only in rats fed on the fat-deficient diet. The results are discussed in relation to the role of acetate in cholesterol and fatty acid metabolism, and it is suggested that the formation of ester cholesterol is dependent on co-enzyme A.

SCHOTZ, M. C., RICE, L. I. and ALFIN-SLATER, R. B. **Further studies on cholesterol in liver cell fractions of normal and cholesterol-fed rats.** *J. Biol. Chem.*, 1953, **204**, 19-26. [Dept. Biochem. Nutrit., Sch. Med., Univ. S. California, Los Angeles.]

The livers were removed from rats which had been fed on stock diet and from rats fed on a synthetic diet containing 0.5 per cent. of bile salt for 5 days and then supplemented with 1.0 per cent. cholesterol for 7 days. Liver homogenates were separated into 5 ultracentrifuge fractions designated nuclear, mitochondrial, submicroscopic particulate, floating and supernatant. Free and esterified cholesterol were estimated in each fraction.

In normal liver more than 60 per cent. of the free cholesterol was found in the submicroscopic particles, and most of the esterified sterol was associated with the floating (centripetally migrating) fraction. After 7 days of cholesterol feeding an increase was found in esterified cholesterol in the centripetally migrating fraction; small increases occurred also in the other cellular fractions.—G. A. Garton.

MANN, G. V., ANDRUS, S. B., McNALLY, A. and STARE, F. J. **Experimental atherosclerosis in Cebus monkeys.** *J. Exp. Med.*, 1953, **98**, 195-218. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston.]

The basal diet contained, per cent., casein 25, sucrose 60.3, salt mixture 4, maize oil 8, cod liver oil 2, choline chloride 0.5, *p*-aminobenzoic acid 0.1 and inositol 0.1. It was modified by reducing the casein to 10 per cent., replacing casein with 10 or 20 per cent. soya bean α -protein low in methionine, increasing the maize oil to 15 per cent., and adding 5 per cent. cholesterol. These variations provided 8 diets.

The mean normal serum cholesterol in *Cebus* monkeys, established by 103 estimations on 69 animals, was 142 mg. per 100 ml., S.D. 51. On a diet low in methionine, containing 20 per cent.

α -protein, 15 per cent. fat and 5 per cent. cholesterol, serum cholesterol rose to 500 mg. per 100 ml. in the seventh week and remained high. Levels above 300 mg. per 100 ml. were also attained in 2 monkeys receiving 10 per cent. casein with high fat and cholesterol. A supplement of 1 g. DL-methionine daily prevented the rise in plasma cholesterol and the loss of weight which accompanied it. DL-Methionine or L-cystine reversed the increase in plasma cholesterol. The increase was facilitated by high fat intake and reduced by high protein intake. Of 9 monkeys which had serum cholesterol levels of 300 mg. per 100 ml. or more for 18 to 31 weeks, 8 were found to have aortic lesions, as had 3 of 8 animals with high blood cholesterol of less than 18 weeks. Gross lipid infiltration of visceral organs was not found.

NELSON, D., IVY, A. C., ALTSCHUL, R. and WILLHEIM, R. **Effect of aureomycin on experimental arteriosclerosis and serum cholesterol levels.** *Arch. Pathol.*, 1953, **56**, 262-267. [Dept. Clin. Sci., Univ. Illinois.]

Groups of 5 rabbits were used in a 20-week experiment to study the effect of combining cholesterol feeding with oral administration of aureomycin. Raising the cholesterol intake from 0.5 to 1.0 per cent. increased the severity and extent of vascular and parenchymal lesions, the average scores for histological rating of the 2 groups being 2.4 and 5.0, respectively, on a rating scale of 1 to 9. Increasing the cholesterol intake significantly increased the cholesterol, total lipid and lipid P of the serum, and the cholesterol:phospholipin ratio. The amount of fat in the liver was also increased. Addition of 0.025 per cent. aureomycin to the diet at both levels of cholesterol intake produced further significant increases in all these indications of cholesterol toxicity, except in liver fat, which did not differ significantly from that of the rabbits given cholesterol without aureomycin. The scores for histological rating in the groups with aureomycin were 4.4 and 8.8, respectively, for intakes of 0.5 and 1.0 per cent. cholesterol. The action of aureomycin in increasing blood cholesterol is probably due to its modification of the intestinal flora.—M. B. Richards.

ROSENMAN, R. H., BYERS, S. O. and FRIEDMAN, M. **Role of cholate in dietary-induced hypercholesteremia of rats and rabbits.** *Amer. J. Physiol.*, 1953, **175**, 307-309. [Harold Brunn Inst., Mount Zion Hosp., San Francisco, Calif.]

Groups of adult rats of Long Evans strain were fed on a stock diet to which was added 2 per cent.

cholesterol or 1 per cent. cholic acid or both, a control group receiving no supplement. Groups of 6-week-old rabbits were given a stock ration alone or with 2 per cent. cholesterol or 1 per cent. cholate, dissolved in heated vegetable oil. After 8 weeks the rats and rabbits were killed, their aortas were examined for arteriosclerosis and blood cholesterol, cholic acid and phospholipins were estimated.

A slight rise in plasma cholate was observed in all rats given excess cholesterol or cholic acid, and in animals given both there was a marked increase in plasma cholate, cholesterol and phospholipins. No evidence of arteriosclerosis was found. In the rabbits, extensive arteriosclerosis developed in the aortas of animals which had received cholesterol. A moderate rise of plasma cholesterol was found in rabbits given cholate and a marked rise in those given cholesterol. The plasma phospholipin level was considerably raised in the cholesterol-fed group. In neither rats nor rabbits was high blood cholesterol related to plasma cholate concentration.

NICHOLS, C. W. (Jr.), SIPERSTEIN, M. D. and CHAIKOFF, I. L. **Effect of dihydrocholesterol (cholestanol) administration on plasma cholesterol and atherosclerosis in the rabbit.** *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 756-758. [Dept. Physiol., Sch. Med., Univ. California, Berkeley.]

Rabbits in 4 groups were fed for 2 weeks on a stock diet supplemented with 5 per cent. Wesson oil to which was added 1 per cent. cholesterol or 2 per cent. dihydrocholesterol or the two sterols together. For the next 5 weeks the rabbits received the stock diet alone, and then for 9 weeks the same experimental diets. Plasma cholesterol was estimated at intervals during the experiment, at the conclusion of which the animals were killed and their aortas and livers were removed. The areas of arteriosclerotic plaques were measured, and total liver lipids were estimated.

Rabbits given the diet containing 1 per cent. cholesterol showed high blood cholesterol values, averaging 1041 mg. per 100 ml., and an average arteriosclerotic plaque area of 271 sq. mm. Cholesterol with dihydrocholesterol gave an average plasma cholesterol value of 120 mg. per 100 ml. and an average plaque area of 4.9 sq. mm., showing that dihydrocholesterol inhibited the effect of cholesterol. Plasma cholesterol was not affected when dihydrocholesterol was given alone, but a few animals in this group developed arteriosclerotic plaques.

The average values for liver lipids were 3.0 per cent. for rabbits not given sterol, 6.7 per cent. for those given cholesterol alone, 3.3 per cent. for

those given dihydrocholesterol and 4.6 per cent. for those given both sterols.—G. A. Garton.

WIKRAMANAYAKE, T. W., MUNRO, H. N., NAISMITH, D. J. and HUTCHISON, W. C. **A note on the influence of energy intake on phospholipid metabolism.** *Biochem. J.*, 1953, **55**, 640-644. [Dept. Biochem., Univ. Glasgow.]

In the first part of this investigation young adult rats were studied at different energy levels on diets with or without protein. The animals and the methods of liver lipid analysis were those described previously (Abst. 4579, Vol. 23).

The amount of liver phospholipin increased in response to increasing energy intake when the diet contained an adequate amount of protein, but not when the diet was protein-free.

In the second study rats with an initial body-weight of 180 g. were fed on diets of which the energy value was varied by altering the amount of carbohydrate, in presence or absence of protein. The animals received injections of 10 μ C. inorganic $^{32}\text{P}\text{O}_4$ per 100 g. bodyweight and were killed with ether 2, 5 or 8 hr. later. The livers were removed and the phospholipins were isolated for ^{32}P estimation and computation of the rate of phospholipin turnover.

The turnover rate was influenced by energy intake on diets containing protein. On protein-free diets the rate of phospholipin formation was not affected by energy intake within the range studied. It is suggested that some dietary substance other than protein was reduced to a level at which it became the limiting factor in phospholipin formation.—G. A. Garton.

PITTONI, A. and ROSSI, C. R. **Sul meccanismo d'azione dei fattori lipotropi. 2. Il metabolismo dei corpi chetonici nel fegato di ratti trattati con lipocaico. [Mode of action of lipotropic substances. 2. Metabolism of ketone bodies in the liver of rats given lipocaic.]** *Arch. Sci. biol., Bologna*, 1953, **37**, 326-331. [Ist. Chim. Biol., Univ. Padua.]

For part 1 see Title 4762, Vol. 23.

In normal rats given 50 mg. lipocaic daily by mouth for 10 to 15 days there was a decrease in the amount of ketone bodies in the liver, and in

both the respiratory intensity and the R.Q. of the organ. Comparison of these data with those from experiments in which the animals were deprived of lipocaic by complete removal of the pancreas indicates that lipocaic acts in the liver by favour-

ing conversion of ketone bodies to glucose and inhibiting transformation of carbohydrate to lipids.

BERGMAN, E. N. and SELLERS, A. F. Studies on intravenous administration of calcium, potassium, and magnesium to dairy calves. 1. Some biochemical and general toxic effects. *Amer. J. Vet. Res.*, 1953, **14**, 520-529. [Dept. Vet. Med., Univ. Minnesota, St. Paul.]

Experiments were performed on 12 calves, ranging in weight from 48 to 240 lb. The jugular vein was cannulated with a polyethylene tube and injections were given from a constant infusion pump until severe signs of toxicity or death occurred.

The maximum dose of Ca tolerated was about 0.07 m. equiv. per kg. bodyweight per min. for 45 min. Death occurred at a total serum Ca level of 14 to 16 m. equiv. per litre, from cardiac failure with heart block and ventricular fibrillation. Development of signs was not progressive, but occurred in a series of crises.

Of 8 experiments with K, only one was fatal, death from cardiac failure following a slow increase in plasma K over 168 min. to 12.7 m. equiv. per litre. Development of signs was progressive, severe irritability, excitability and diuresis accompanying plasma K levels of about 8 m. equiv. per litre.

One of 5 experiments with Mg was fatal, death occurring from respiratory failure after injection at 0.14 m. equiv. per kg. per min. for 17 min. The rate of injection determined the severity of the

reaction and the total dose in the fatal experiment was only one-third that in non-fatal experiments. In the latter, light anaesthesia accompanied plasma levels of 10 to 13 m. equiv. per litre, with extreme cyanosis and dyspnoea. When Mg and Ca were given simultaneously ventricular fibrillation occurred, but the presence of Ca appeared to decrease the anaesthetic effect of Mg.

Na oxalate in 2 calves greatly depressed serum Ca and produced cyanosis and dyspnoea, but not death.

The interrelations of the blood electrolytes are discussed.—D. Duncan.

FEDOROV, N. A., GRABETSKII, A. A., LISENKO, N. V., DAGAEVA, L. N., BOBOVSKII, E. V., ROZHANSKII, M. E. and PROKHONCHUKOV, A. A. Issledovanie mineral'nogo obmena v tverdykh tkanyakh zuba s pomoshchyu radioaktivnykh indikatorov. [Studies on mineral metabolism in the hard tissues of the tooth with the aid of radio-active tracers.] *Stomatologiya*, 1953, No. 1, 3-17.

Experiments in which ^{32}P , ^{45}Ca , ^{86}Sr , and ^{35}S were used as radio-active indicators showed that renewal of the components of the dental tissues, including the enamel, proceeds without interruption. During prolonged experiments on dogs the dynamics of P and Ca metabolism was studied in the solid tissues of the teeth and the time for maximum inclusion of these elements was estimated. P metabolism in the dental tissues of young dogs is much more intense than in grown dogs. Experiments on dogs with fistulae in the salivary duct of the parotid gland showed a regular uptake of P and Ca in the saliva after subcutaneous introduction of these elements. The enamel gets most of its inorganic elements from saliva, although the dentine canals play some part. Enamel of the lower teeth, being more in contact with saliva than the upper teeth, takes up more ^{32}P than the enamel of the upper teeth. Enamel of teeth which have been de-pulped and then filled retains its capacity to absorb the elements from saliva, but radio-activity cannot be detected in dentine. Enamel on teeth which have been shielded from saliva by metal caps exhibits little or no radio-activity. P was taken up more intensely in solid dental tissue during experimental vitamin B₁ deficiency than in control tests. Experiments on denervation of

N.A. and R., April 1954

dental tissue showed the significance of nerve in the regulation of dental tissue. (From authors' summary.)—W. Hughes.

LENGAR, N. G. C. and RAU, Y. V. S. **Green leafy vegetables as sources of calcium.** *Ann. Bio-*

Vol. 24, No. 2

chem. Exp. Med., 1952, **12**, 41-52. [Military Food Lab., Poona.]

Data are presented for the contents of dry matter, total and water-soluble oxalates, total Ca and Ca remaining after water and acid extractions in 18 oven-dried samples of vegetables and 1 sample of betel leaves. A high content of Ca in a vegetable does not necessarily mean that the vegetable will be valuable as a source of Ca. Its value is likely to be high only if the ratio total Ca : total oxalic acid is greater than 1; if it is less than 0.2 the value will be poor. The value of betel leaf is attributable to CaCO_3 used in its preparation, not to its natural Ca content.

In growth experiments with rats the diets of 2 groups were basically similar and each contained 15 per cent. *Amaranthus polygamus*; they differed in that 62 per cent. of one was rice, of the other, maize starch. Growth and survival rates were better with rice than with maize starch, a finding which supports the view of Rau and Murty (Abst. 425, Vol. 13) that rice has a supplementary value in such diets.—D. Harvey.

STEVENS, J. **The secretion of radio-active phosphorus in saliva and gastric juice in man.** *Clin. Sci.*, 1953, **12**, 375-383. [Dept. Surg., Univ. Glasgow.]

The subjects were men aged 45 or over, 8 of whom had duodenal ulcer, 4 gastric ulcer, 3 carcinoma of the stomach and 6 "non-gastric" complaints. After at least 5 hours' fasting the stomach was emptied and kept empty by continuous aspiration for 15 min. before ^{32}P injection and 3 hr. afterwards. ^{32}P was given by vein as orthophosphoric acid in normal saline, providing 100 μC . ^{32}P . Saliva was collected continuously and 4 blood samples were taken in the 3-hr. period.

In 8 out of 9 subjects the activity of the first saliva specimen, obtained 5 to 20 min. after injection, was greater than that of blood at that time. The ratio of salivary to blood concentration of ^{32}P varied within fairly narrow limits, the mean for 9 patients being 3.6. It was not correlated with rate of saliva collection.

In all the subjects ^{32}P appeared in the gastric juice within 5 min. and reached its highest concentration between 30 and 60 min. after injection. The maximum ratio of ^{32}P in gastric juice to ^{32}P in blood, also reached in the second half-hour, was low in subjects with high acidity and high in subjects with achlorhydria.

When saliva or gastric juice was treated with trichloroacetic acid the radio-activity was confined to the fluid.—D. Duncan.

VAN BEKKUM, D. W. and QUERIDO, A. **Inorganic phosphate response to intravenous glucose administration in progressive muscular dystrophy.** *J. Clin. Invest.*, 1953, **32**, 1061–1064. [Dept. Dis. Metabol., Med. Clin., Univ. Hosp., Leyden.]

Ten normal subjects and 5 patients with progressive muscular dystrophy were instructed to ingest liberal amounts of carbohydrate for 3 days before the test, which was performed after a 12-hr. fast. Glucose and inorganic P were estimated in the blood before and 15, 30, 60, 90 and 120 min. after intravenous injection of 0.5 g. glucose per kg. bodyweight.

The mean glucose tolerance curve in dystrophic subjects was not significantly different from normal, though there was a delayed response in one subject. The mean maximum fall in plasma inorganic P, however, was only 10 per cent. in the dystrophic subjects, compared with 28 per cent. in controls, a highly significant difference.

CREMER, H. D., BÜTTNER, W., WEBER, H., DITTMANN, G. and HANNOVER, R. **Ernährungsfaktoren bei Zahn- und Knochenbildung. 3. Einlagerung von P^{32} in Zähne sowie in normalen und frakturierten Knochen bei ver-**

schiedener Mineralzufuhr. [Diet components in the formation of teeth and bones. 3. Deposition of ^{32}P in teeth and in normal and fractured bones after supply of different minerals.] *Biochem. Ztschr.*, 1953, **324**, 337–343. [Physiol. Chem. Inst., Univ. Mainz.]

For previous parts see Absts. 899, Vol. 22; 635, Vol. 24.

The radio-activity in bones and teeth after intraperitoneal injection of ^{32}P was studied in young rats from 17 to 21 days old and adult rats from 6 to 8 months old. This activity, a measure of the metabolic intensity of the organs, can be used to detect the presence of metabolic anomalies, such as tooth caries, and to measure the intensity of healing processes after fracture. Further experiments, with different diets and mineral supplements, indicated that measurement of the activity in fractured bones at a definite time after the fracture and parenteral administration of ^{32}P was a useful test of the effect of diet components.

PARK, E. A. and RICHTER, C. P. **Transverse lines in bone: the mechanism of their development.** *Bull. Johns Hopkins Hosp.*, 1953, **93**, 234–248. [Dept. Pathol., Sch. Med., Johns Hopkins Univ., Baltimore, Md.]

A study was made of the transverse line which frequently appears in bone after acute illness, and which is readily detectable on X-ray examination. The lesion was produced in young rats weighing from 130 to 150 g. by a diet of dextrose and vitamin B₁ chloride. After 58 days longitudinal bone growth had almost ceased and the animals had lost about 40 per cent. of their weight. Some rats were killed at this stage and their bones were examined, others were returned to stock diet and the bones were studied in recovery in animals killed at intervals.

The chief changes in the long bones of rats on the experimental diet were resorption of the trabeculae and a greatly narrowed proliferative cartilage plate encasing a thin layer of bone. This thin layer formed the transverse line. Centrally it was fragmentary, with gaps for capillaries, but at the sides it formed a solid encasement. The cause of its formation was the slowing or cessation of cartilage growth at an earlier stage than that of osteoblast activity.

When recovery began, osteoblasts settled on the bony film and began to produce osteoid, so that the line at first widened. Later, the cartilage cells re-established their cycle and osteoblasts and capillaries penetrated the cartilage and formed bone on the matrix frame. At this stage the transverse line ceased to widen, and it finally disappeared after some 25 days.—W. A. Greig.

DIStEFANO, V., NEUMAN, W. F. and ROUSER, G. **The isolation of a phosphate ester from calcifiable cartilage.** *Arch. Biochem. Biophys.*, 1953, **47**, 218-220. [Div. Pharmacol. Toxicol., Dept. Radiation Biol., Sch. Med. Dent., Univ. Rochester, N.Y.]

A compound has been found in hydrolysates of rachitic rat cartilage which appears to be a stable phosphate ester of a hexosamine which, in the cartilage, is bound to material insoluble in trichloroacetic acid. Incubation of the cartilage overnight in saline, which destroys its power of calcification, results in loss of the phosphate, but the presence of 1 per cent. CaCl_2 protects it.

A role of this phosphate in calcification is suggested.—D. Duncan.

FREERKSEN, E. and MEISSNER, J. Über die Verteilung von radioaktivem Phosphat in gesunden und tuberkulösen Tieren. [Distribution of radio-active phosphorus in healthy and tuberculous animals.] *Ztschr. ges. exp. Med.*, 1953, **121**, 442-452. [Inst. Exp. Biol., Tuberkulose-Forschungs-Inst., Borstel, Bad Oldesloe.]

In extension of studies on healthy rabbits (Abst. 3255, Vol. 23), 10 rabbits with advanced tuberculosis were compared with 9 healthy ones. Distribution of ^{32}P differed significantly only in marrow and plasma, in which ^{32}P activity relative to that of whole blood was higher in the infected animals. That this was not a secondary change due to emaciation was shown by the fact that the values for 2 rabbits with hunger oedema were within the range for healthy rabbits. The lungs of the oedematous rabbits, however, showed high activity; the heavily diseased lungs of tuberculous rabbits showed about the same activity as those of the healthy.

Marrow activity relative to plasma activity was much the same in both healthy and tuberculous rabbits, but activity of other tissues and organs was less in the infected animals.

Decrease of phosphorylation of fat and carbohydrate with maintenance of nucleic acid formation is the explanation suggested for these findings.

VAN REEN, R. and PEARSON, P. B. **Magnesium deficiency in the duck.** *J. Nutrition*, 1953, **51**, 191-203. [McCollum-Pratt Inst., Johns Hopkins Univ., Baltimore, Md.]

Day-old ducklings received a diet of purified nutrients containing no Mg or up to 120 mg. Mg in 100 g. After 14 days they were killed and brain enzymes and riboflavin, nicotinic acid and free and bound pantothenic acid in liver were estimated.

Growth was retarded when the diet contained less than 50 mg. Mg. per 100 g. In Mg deficiency alkaline phosphatase and diphosphopyridine nucleotidase activities in brain tissue were low. The effect on phosphatase was greater and occurred earlier than that on nucleotidase. The vitamin B complex compounds estimated in the liver were not affected.—R. Hill.

SRIKANTIA, S. G., VENKATACHALAM, P. S. and GOPALAN, C. **Electrolyte studies in nutritional edema.** *Metabolism*, 1953, **2**, 521-528. [Nutrit. Res. Labs., Indian Council Med. Res., Coonoor, S. India.]

The subjects were Indians suffering from deficiencies of energy and protein. Blood Na was estimated in 30 on admission to hospital and in 12 of them after oedema had cleared; chloride was estimated in 19 and 11, and K in 8 and 7, respectively. Additional studies were made with 12 patients with oedema and on a diet containing 6.2 g. salt daily, of whom 6 were given 10 g. additional NaCl daily and 6 had 45 g. daily, in 3 doses, of Resodex, an NH_4K cation exchange resin which restricted Na absorption.

Serum Na was at the lower level of normal range when oedema was present and fell lower still when oedema cleared; chlorides were below normal both before and after, and K, which initially was at the upper level of normal range, showed a slight fall after oedema disappeared. High NaCl intake caused a temporary increase in retention of both water and salt, but when continued did no harm. Reduction of Na absorption produced polyuria, but this beneficial effect was also transient.

The low Na concentration in serum in these patients with nutritional oedema and the fact that

the oedema does not respond to treatment with resin suggest that retention of Na is not its cause.

LEVIN, M. H., RIVO, J. B. and BASSETT, S. H. **Metabolic studies in gout with emphasis on the role of electrolytes in acute gouty arthritis.** *Amer. J. Med.*, 1953, **15**, 525-534. [Veterans Admin. Centre, Los Angeles, Calif.]

Records were made of balances of N, Na, Cl and K over 90 days in 1 patient and of Cl balance and uric acid excretion in another over 161 days and of Cl balance in a control subject over 59 days. During these periods adrenocorticotrophic hormone, testosterone, colchicine, pitressin and a mercury diuretic were administered separately to the patients and the control subject was given colchicine or the mercury diuretic. There was no evidence that "mineralocorticoid" activity of the adrenal cortex was related to the occurrence of acute attacks of gouty arthritis.—D. Harvey.

FANCONI, G. and NEUHAUS, T. **Kalium und Tetanit. [Potassium and tetany.]** *Helv. paediat. Acta*, 1953, **8**, 424-450. [Kinderklinik, Univ. Zürich.] French, Italian and English summaries.

After reviewing the literature on the relationship between K and nervous excitability, the authors describe 13 cases which tend to confirm this relationship. In pseudo-uraemic eclampsia renal insufficiency causes retention of K in the extracellular fluid, and this retention can favour, or even cause, convulsions. Early spasmophilia, generally characterised by high phosphate, low Ca and high K in the serum, is probably due to transient or persistent parathyroid insufficiency and inability of the infant's kidneys to excrete excess phosphate. Excess of K, either absolute or relative to serum Ca, appears to favour the appearance of convulsions. In toxicosis the high serum K in the post-acidotic stage, especially after intravenous injection of K solutions, also may induce convulsions. In several older children with disturbance of the sympathetic nervous balance and tetany with normal serum Ca, a moderate increase was found in serum K.—M. B. Richards.

FOURMAN, P. and ROBINSON, J. R. **Diminished urinary excretion of citrate during deficiencies of potassium in man.** *Lancet*, 1953, **265**, 656-657. [Med. Res. Council, Dept. Exp. Med., Univ. Cambridge.]

Total deficits of 300 and 450 m. equiv. K were induced in 2 normal men by ingestion of a low-K diet and a cation exchange resin. Their excretion of citrate was reduced from 160 and 380 mg. daily, respectively, to between 38 and 70 mg. Control values were not restored until the K deficit had been completely made good. There was no associated fall in plasma citrate.

A woman with renal acidosis, losing excessive amounts of K in urine, excreted from 4 to 74 mg. citrate daily and did not excrete more when she had been given 15 g. KCl daily for some time.

ROOT, M. A. **Comparison of the in vivo sodium-removing activity of various types of ion exchange resins in rats.** *J. Lab. Clin. Med.*, 1953, **42**, 430-437. [Lilly Res. Labs., Eli Lilly and Co., Indianapolis, Ind.]

Pairs of male Wistar rats received according to appetite a ground standard diet to which resins were added. Food, faeces and urine were analysed for Na, K, Cl and phosphate.

The standard resin was Amberlite XE-64. Amberlite XE-112 and XE-103 were about twice as effective as the standard for binding Na in the digestive tract. The 3 sulphonic acid resins were not more effective than the standard, and phosphonic acid resins were much less effective. Two liquid resins, given in the drinking water, were as effective as the standard on a dry-weight basis, but would be impractical clinically because of the large volume of fluid which would have to be used with them. The addition of the anion exchange resin Amberlite XE-58 did not increase the

N.A. and R., April 1954

Na-binding capacity of Amberlite XE-64 and XE-88.

The amount of Na bound by 1 g. resin increased with increasing Na intake, but the percentage of ingested Na excreted in the faeces decreased; if low Na absorption is desired, the use of resins should therefore be accompanied by a low Na intake.—D. Duncan.

GABOVICH, R. D. Eksperimental'noe issledovanie toksichnosti malykh kontsentratsii ftora. [An experimental investigation of the toxicity of small concentrations of fluorine.] *Gigiena Sanit.*, 1953, No. 1, 9-15. [Kaf. Obshch. Gig., Med. Inst., Kiev.]

Eight groups of rats were given F in drinking water in amounts varying from 0.01 to 40 or 50 mg. per kg. liveweight. Experiments continued over 9 months. With 0.11 to 0.29 mg. F per kg., faint striations were observed on some parts of the enamel of the incisors and there was accumulation of F in the tissues. With 0.44 mg. per kg. (i.e., 6 mg. per litre water, the highest concentration of F found in any reservoir in the U.S.S.R.), in addition to striations of the enamel there were slight biochemical changes and changes in enzyme activity and bone composition. With 1 mg. per kg. there were slight changes in the thyroid, kidneys and bones. With 3.75 to 11.3 mg. per kg. in addition to changes in the teeth there was a considerable decrease in enzyme activity, shown by changes in the internal organs and bones, and death from cachexia and pneumonia. At the rate of 40 to 50 mg. per kg. acute poisoning led to death in a few days.—W. Hughes.

MILLER, R. F. and PHILLIPS, P. H. The metabolism of fluorine in the bones of the fluoride-poisoned rat. *J. Nutrition*, 1953, 51, 273-281. [Dept. Biochem., Univ. Wisconsin, Madison.]

For 6 weeks 36 weanling albino rats were given a ration containing 0.1 per cent. NaF (450 p.p.m. F), and 14 comparable controls were given the same ration without added NaF, containing 3 to 5 p.p.m. F. Both groups were then given the un-supplemented ration for 32 weeks, during which animals were killed every 4 weeks for femur analysis.

Administration of F caused the incisors to become chalky and retarded skeletal growth and calcification. Upon withdrawal of F there was a rapid return of the incisors to normal appearance, and by 17 weeks of age the skeletons of treated and control animals were similarly calcified and of

normal size. At the end of 6 weeks of F administration the F content of the femur was 1.80 mg., or 15,400 p.p.m. fat-free dry weight, compared with 0.04 mg. and 225 p.p.m. for controls. Four weeks later the values for previously F-treated animals were 1.20 mg. and 5000 p.p.m.; after 8 weeks they were 1.00 and 3000. Thereafter total F increased slightly and F concentration decreased to values of 1.07 mg. and 2300 p.p.m. at 32 weeks. In controls during the same period F concentration in the femur increased to 350 p.p.m. and total F in the femur to 0.20 mg.—F. C. Aitken.

ACKERMANN, P. G. and IVERSEN, K. Radio-iodine excretion in the aged. *J. Gerontol.*, 1953, 8, 458-464. [Div. Gerontol., Sch. Med., Washington Univ., St. Louis, Mo.]

The subjects, 24 men and 25 women over 60 years of age, without sign or symptom of thyroid or renal disease, were given approximately 25 μ C. of carrier-free radio-active iodine by mouth in the morning. They were allowed to eat the usual hospital breakfast 1 hr. later and the usual diet for the next 3 days, while urine collections were made. Basal metabolic rates and renal clearance rates were estimated. Less labelled I was excreted than was observed by other investigators in young adults, but no significant change was noted with increasing age over 60 in renal excretion rate or thyroid I uptake.—B. W. Simpson.

STORAASLI, J. P., ROSENBERG, S. and FRIEDEL, H. L. Effect of food and water on thyroid

uptake of radioiodine (I^{131}) in rats. *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 748-750. [Dept. Radiol., W. Reserve Univ., Cleveland, Ohio.]

Male rats of Wistar strain weighing from 120 to 150 g. were fed for 4 weeks on a diet low in I, and were then divided into 8 groups of 3 and given single intraperitoneal injections of 0.1 μ C. I^{131} per g. bodyweight. The experiments lasted 6 or 24 hr. after injection. Two groups received no water and no food for 36 hr. before the administration of I^{131} and none for the next 6 or 24 hr.; 2 groups received food and water up to the time of injection, but none afterwards; 2 groups received food and water up to the time of injection, but only water after the injection; and the last 2 groups received food and water all the time. The measurements of radio-activity in the thyroids and excreta were made by a scintillation counter, and the results were recorded as a percentage of the administered dose in each organ examined.

At the end of the experiment the control rats receiving neither food nor water had accumulated, in 6 and 24 hr., 56 and 51 per cent. of the dose of I^{131} , respectively. The rats given water alone had collected 30 and 16 per cent., and those given food and water 18 and 7 per cent. There was a correspondingly increased excretion of I^{131} when water alone or food and water together were administered. The amount of stable I in the food and water had no influence on the uptake of I^{131} by the thyroid.

As the rate of radio-active I uptake by the thyroid gland is used for evaluating thyroid status, it follows from these studies that the procedure should be standardised as far as possible by restricting the amounts of fluid and food consumed before and during the test.—B. W. Simpson.

SEN, D. P. Studies on food-iron. 1. Absorption of iron by rats. 2. Excretion of iron by rats. 3. Biological availability of iron in rice (*Oryza sativa*) and ferric chloride as measured by the amount of iron retained in liver, spleen and body. 4. Effect of proteins on the haemopoiesis due to the iron in rice (*Oryza sativa*). 5. Haemopoietic effect of iron in rice (*Oryza sativa*), wheat (*Triticum vulgare*), lentil (*Lens esculenta*), ferric-phytate, egg-yolk of duck, lecitho-vitellin protein and ferric chloride. *Ann. Biochem. Exp. Med.*, 1952, **12**, 29-36; 53-58; 59-62; 67-74; 103-110. [Dept. Appl. Chem., Univ. Coll. Sci. Technol., Calcutta.]

1. Rats were maintained on milk, containing not more than 0.04 mg. Fe per litre, for 3 to 4 weeks after weaning, and were then divided into a control group of 5 and 2 experimental groups of 8 rats. The experimental diet consisted of a limited amount of whole dried milk, and liquid cow's milk to appetite. The two experimental groups received daily 0.2 mg. Fe, as ferric ammonium citrate and as haematin, respectively. After 4 weeks all were killed.

The Fe content of liver, spleen and carcass and the blood Hb value were much higher in the rats given ferric ammonium citrate than in either of the other groups. Little or no Fe appeared to have been retained from haematin.

In a second experiment, with adult rats, there was little difference in total Fe content between those which received ferric ammonium citrate and those which received no Fe supplement.

2. Adult rats were maintained on cow's milk. After the first week one group continued on this regimen, a second and third received supplements of ferric ammonium citrate by mouth and intraperitoneal injection, respectively, and haemolytic anaemia was produced in the fourth group by injection of phenylhydrazine. Fe content of faeces and urine was estimated, and the rats were killed after a week of this treatment.

There was little difference in Fe excretion in urine between the groups, except for an increased excretion in the group which received Fe by injection, when 8.8 per cent. of the injected dose ap-

N.A. and R., April 1954

peared in the urine. Absorption of Fe taken by mouth by the second group was negligible, almost all the Fe appearing in the faeces. There was some Fe in the faeces of all rats, indicating excretion from the tissues. Although groups 3 and 4 had increased Fe in spleen and liver there was no increase in faecal Fe, which suggested a limited power of excretion by the intestinal tract.

3. The Fe in cooked rice was less available to rats than a similar quantity of Fe given by mouth as ferric chloride.

4. Rats made anaemic by a milk diet were divided into 3 groups of 6 animals. They received diets each containing rice 80, yeast 3 and salt mixture 3 parts. Protein was supplied, respectively, by dried iron-free egg yolk 14, egg albumin 13, or low-iron casein 14 parts. Each provided just over 5 mg. Fe per 100 g. diet.

Hb regeneration was somewhat greater on egg yolk than on the other diets, but Fe consumption in this group was also slightly greater. Fe contents of carcass, spleen and liver were not significantly different between groups.

5. In experiments similar to those in paper 4 above, egg yolk, lecitho-vitellin and ferric chloride were more effective in promoting Hb regeneration than were cereal grains or ferric phytate. There was a close relation between haemopoietic effects and availability of Fe in the different foods.

D. Duncan.

2138

DICK, A. T. **The control of copper storage in the liver of sheep by inorganic sulphate and molybdenum.** *Austral. Vet. J.*, 1953, **29**, 233-239. [Div. Animal Health, C. S. I. R. O., Animal Health Res. Lab., Parkville, Victoria.]

Copper was estimated in liver biopsy samples taken at the beginning and end of an experiment of 3 months' duration with 6 groups of 5 wethers. Sheep with equal intakes of Cu stored more Cu in the liver when the diet was oat hay than when it was alfalfa hay. When the molybdenum intake was raised from 0.5 to 10.5 mg. daily, storage of Cu was significantly decreased only in animals on a diet of alfalfa hay.

In a second experiment with groups of 3 sheep, Mo limited Cu storage in sheep on oat hay as well as on alfalfa hay if the sulphate intake from oat hay was supplemented with inorganic sulphate so as to equal that from alfalfa hay.—F. C. Aitken.

FRICK, E. and LAMPL, F. **Über die Entwicklung des Gehirns von Ratten bei Kupfermangel. [Development of the brain in rats deprived of copper.]** *Klin. Wochenschr.*, 1953, **31**, 912-913. [Neurol. Klin., Univ. Hamburg, Eppendorf.]

Vol. 24, No. 2

Young and adult rats were reared and maintained on a milk diet for several generations; first and third generation animals were studied. All the animals developed Fe deficiency anaemia. The mean serum Cu in young rats was 51.43 μ g. per 100 ml., range 19 to 70 and in old rats 54.43, range 30 to 77. The mean for healthy normal rats was 245.8, range 184 to 395. None of the rats deprived of Cu showed signs of nerve lesions, and histological examination of the brain and cord showed no abnormality. It is concluded that for production of swayback disease some influence additional to deficiency of Cu must operate.

OTHER MINERALS

2140

DITTRICH, H. **Die Wirkung kleinster Kobaltgaben auf Blutbildung und Eisenstoffwechsel. [Effect of minute amounts of cobalt on blood formation and iron metabolism.]** *Deutsch. med. Wochenschr.*, 1953, **78**, 1658-1660. [Evangel. Krankenhaus, Vienna.]

A new synthetic compound of Co and chlorophyll, when used in the treatment of several types of anaemia, gave completely satisfactory results in the low dosages of 200 and 400 μ g. Co, given intramuscularly. Such minute amounts of Co, given in the form of a simple salt or in other complex compounds, are ineffective. The effectiveness of the Co-chlorophyll compound is probably due to the combination of Co with the porphyrin III ring, and it is suggested that there may be a relationship with vitamin B₁₂. The compound is well tolerated, and apparently quite innocuous.

ARRINGTON, L. R. and DAVIS, G. K. **Molybdenum toxicity in the rabbit.** *J. Nutrition*, 1953, **51**, 295-304. [Dept. Animal Husb., Florida Agric. Exp. Stat., Gainesville.]

Dutch rabbits were given a basal ration of commercial pellets to appetite, with greens once a week. Twenty-four weanling rabbits in groups of 2 to 5 were given sodium molybdate at levels of 0.14, 0.05, 0.10, 0.20 and 0.40 per cent. Mo in the ration. Five weanling rabbits were controls and 2 others were given 0.20 per cent. Mo and 0.02 per cent. Cu in the ration. Groups of 2 or 3 mature rabbits were given the basal ration supplemented with Mo at different levels and 4 were controls.

Rabbits given 0.1 per cent. Mo or more showed signs of poisoning: anorexia, loss of weight, alopecia, slight dermatosis and anaemia. In some of the young rabbits there was also abnormality of the front legs. The 2 given 0.02 per cent. Cu with the Mo showed no sign of poisoning.

Of the 5 weanling rabbits given 0.1 per cent. Mo, 3 were given a drench of copper sulphate when their condition was serious. There was rapid recovery except that the leg abnormality, present in 2, persisted. The 2 other rabbits in this group showed only moderate signs of poisoning and gradually recovered without treatment. All rabbits given 0.4 per cent. and 6 out of 8 given 0.2 per cent. Mo died.

The Mo and Cu contents of the basal ration were 2.7 and 16.4 p.p.m., respectively.

KYANK, H. Gravimetrische Neutralschwefelbestimmungen im Urin normaler Schwangerer und bei Schwangerschaftstoxikosen. [Gravimetric estimation of neutral sulphur in the urine of normal pregnant women and women with pregnancy toxæmia.] *Arch. Gynäkol.*, 1953, **182**, 793-800. [Frauenklin., Univ. Leipzig.]

Urinary excretion of neutral S was the same in healthy non-pregnant women as in healthy women

in late pregnancy, the average values for 50 subjects being 13.3 and 13.1 per cent., respectively, of the total S excretion. For 50 women in early pregnancy the average was 14.8 per cent. For 21 normal pregnancies the average neutral S excretion in the parturition period was 16.3, and in the first 24 hr. *post partum* 14.5 per cent. For 15 patients with toxicosis the corresponding values were 21.4 and 18.4 per cent. In pregnancy toxicosis, especially with marked oedema, the neutral S excretion was high in the early days in hospital, the average for 30 patients on admission being 24.0 per cent. These high values point to faulty oxidation in pregnancy. In general excretion fell to normal in a few days, when rest in bed and diet had reduced the oedema, although other signs of toxicosis did not completely disappear. A diet containing about 68 g. protein did not then increase neutral S excretion, which showed that the toxicosis patients, under these conditions, were capable of oxidising quantitatively the protein of the diet.—M. B. Richards.

2147

KEENER, H. A., TEERI, A. E., HARRINGTON, R. V. and BALDWIN, R. R. **Metabolic fate of S^{35} in the lactating cow when fed $S^{35}O_2$ preserved silage.** *J. Dairy Sci.*, 1953, **36**, 1205-1211. [Dept. Dairy Husb., New Hampshire Agric. Exp. Stat., Durham.]

Three small silos were filled with chopped clover with a little timothy grass. After the forage was compacted it was injected with 2, 4 or 6 lb. $^{35}SO_2$ per ton of forage. After 5 months the silos were opened and the contents were offered to cows during 30 hr. Urine, faeces and milk were collected from each cow and periodic blood samples were taken for 14 days.

Most of the ^{35}S was recovered as sulphate in water-soluble form in the silage. When the silage was eaten about two-thirds of the ^{35}S was absorbed and for the most part excreted in the urine. About 1 to 5 per cent. was secreted in the milk, and from 10 to 12 per cent. of this was in protein. Most of the activity in the urine and milk was found within 54 hr. after the last of the $^{35}SO_2$ silage was consumed, but active S was found in the faeces for a further 2 days.—W. Godden.

2148

DZIEWIATKOWSKI, D. D. **Sulfate-sulfur metabolism in the rat fetus as indicated by sulfur-35.** *J. Exp. Med.*, 1953, **98**, 119-128. [Hosp., Rockefeller Inst. Med. Res.]

To determine whether sulphate S can be transferred from the maternal organism to the foetus, the distribution of sulphate S in the tissues and embryos of pregnant rats was studied at different

stages of gestation. ^{35}S was found in embryos 24 hr. after its intraperitoneal injection as Na sulphate into pregnant rats, the amount present being directly related to the stage of foetal development. A large fraction of the ^{35}S in the embryo was insoluble in 5 per cent. trichloroacetic acid. This fraction increased with the age of the embryo from about 40 per cent. in the 10-day embryo to 90 per cent. at 20 days. The possibility thus suggested, that some of the isotope was in chondroitin sulphate, was strongly supported by autoradiographs of embryo sections fixed in formaldehyde, which showed that ^{35}S was most highly concentrated in the cartilaginous parts of the skeleton. Estimation of the ^{35}S content of individual tissues showed that the concentration in the humeri of 20-day embryos, still largely cartilaginous, was about 30 times that in the maternal sternum. The concentration in skeletal muscle, brain, heart and skin was also higher than in the corresponding maternal tissues, but was lower in the embryonic intestinal tract than in that of the adult.

GEYER, C. F. **Vanadium, a caries-inhibiting trace element in the Syrian hamster.** *J. Dent. Res.*, 1953, **32**, 590-595. [Freie Univ., Berlin.]

Investigations were prompted by the work of Rygh (see Absts. 719 and 438, Vol. 20).

Of 10 animals, 2 were controls and 8 were given a caries-producing diet for 24 days, the time taken for the appearance of fissure caries on the molars. Half the hamsters were then given daily supplements of 0.08 mg. V_2O_5 , and 25 days later all were killed. Those on the caries diet without V had severe lesions, but in those receiving V caries of the enamel had not advanced into the dentine. Similar results were obtained when the daily dose was 0.04 mg. V_2O_5 : subcutaneous injections of 0.07 mg. at weekly intervals were found also to be protective.—D. Harvey.

GRANDE, F. El papel fisiológico del cinc y sus relaciones con el metabolismo hidrocarbonado. [The physiological role of zinc and its relation to carbohydrate metabolism.] *Rev. española Enferm. Apar. digest. Nutricion*, 1953, **12**, 433-469. [Dept. Fisiol., Fac. Med., Saragossa.] English summary.

From consideration of all the known data it is concluded that, in spite of the many indications in the literature, there is as yet no definite proof of a relation between Zn and carbohydrate metabolism. It is considered that many of the data have been wrongly interpreted and that others are incompatible with present-day knowledge. There is no proof that Zn forms part of the molecule of

insulin as formed by the pancreas, nor is Zn necessary for the physiological action of insulin. The high Zn content of the pancreas appears to be related to the exocrine activity of the gland, since there are proofs of its accumulation in the acinar cells but not in the islets. Deficiency of Zn does not disturb carbohydrate metabolism in experimental animals, according to present knowledge, and no change in Zn metabolism has so far been demonstrated in human diabetes. The combination of Zn and alloxan does not explain the diabetogenic action of this substance. This is deduced from the facts that alloxan does not inhibit the activity of carbonic anhydrase, the only compound of Zn known to have a physiological action, and that of the numerous agents capable of combining with Zn, only oxine and dithizone have shown diabetogenic activity, according to some authors, and the diabetogenic effect of these 2 compounds is apparently confined to the rabbit. It is not found in other species which are undoubtedly sensitive to the diabetic action of alloxan.

ODENTHAL, F., BEIGLBÖCK, W., CLOTTEN, R. and CREUTZFELDT, W. Die Wirkung von radioaktivem Zink 65 auf den Blutzucker und die Langerhansschen Inseln beim Kaninchen. [Action of radio-active ^{65}Zn on the blood sugar and islets of Langerhans in the rabbit.] *Klin. Wochenschr.*, 1953, **31**, 864-865. [Med. Klin., Univ. Freiburg i. Br.]

Radio-active ^{65}Zn as the sulphate or acetate was injected intravenously into 15 rabbits in a dose of 12 to 30 mg. Zn with activity from 50 to 150 μC . The animals suffered no visible or histologically detectable injury. There was no effect on the blood sugar, and no sugar appeared in the urine. Excreted ^{65}Zn was almost entirely in the faeces.—E. M. Hume.

VAN REEN, R. **Effects of excessive dietary zinc in the rat and the interrelationship with copper.** *Arch. Biochem. Biophys.*, 1953, **46**, 337-344. [McCollum-Pratt Inst., Johns Hopkins Univ., Baltimore, Md.]

Young rats received for 4 to 5 weeks diets containing from 500 to 700 mg. Zn per 100 g. diet. Cu was added to some diets as well as Zn. Catalase, cytochrome oxidase, diphosphopyridine nucleotidase, isocitric dehydrogenase and alkaline phosphatase were estimated in the liver. Hb was also estimated.

Catalase and cytochrome oxidase activities and Hb were significantly less in rats which received Zn than in controls. Growth rate was also lower. It is suggested that the lower enzyme activity was not due to a direct inhibitory effect of Zn ions, or

to the formation of inhibitory substances in the liver. Other possible reactions are discussed briefly.

Cu, 0.2 or 0.4 mg. daily, given with Zn, 500 mg.

per 100 g. food, gave normal enzyme activities and prevented anaemia, but the rate of growth was still low.—R. Hill.

SOLOWAY, S. and STETTEN, D. (Jr.) **The metabolism of choline and its conversion to glycine in the rat.** *J. Biol. Chem.*, 1953, **204**, 207-214. [Div. Nutrit. Physiol., Pub. Health Res. Inst. City of New York, Inc.]

Adult male rats were maintained on Purina chow. Each received a single injection of isotopically labelled material with 0.35 mM sodium benzoate per 100 g. bodyweight after a 24-hr. fast. The fast continued for another 24 hr., during which urine was collected, and hippuric acid was recovered.

Choline and betaine were excellent precursors of glycine, comparable in efficiency to serine. Dimethylethanolamine was relatively inefficient. In rats poisoned with aminopterin the isotope dilutions in the hippuric acid recovered after injection of glycine, betaine or choline did not differ from those in normal animals. It is believed that choline is oxidised to betaine before demethylation to glycine.—D. Duncan.

DU VIGNEAUD, V., KINNEY, J. M., WILSON, J. E. and RACHELE, J. R. **Effect of the presence of labile methyl groups in the diet on labile**

methyl neogenesis. *Biochim. biophys. Acta*, 1953, **12**, 88-91. [Dept. Biochem., Cornell Univ. Med. Coll., New York.] French and German summaries.

Eight rats received a diet containing homocystine and choline, but no methionine; the percentage composition was sucrose 73, salt mixture 4, glycine 0.1, L-hydroxyproline 0.1, L-proline, 0.2, DL-serine 0.2, L-aspartic acid 0.2, DL-alanine 0.4, L-tryptophan 0.4, L-arginine HCl 0.6, L-histidine HCl 0.7, L-tyrosine 1.0, DL-threonine 1.4, DL-phenylalanine 1.5, DL-isoleucine 1.8, DL-valine 2.0, L-glutamic acid 2.0, L-leucine 1.3, L-lysine HCl 1.9, NaHCO₃ 1.4, water-soluble vitamins 1, maize oil 3, DL-homocystine 1 and choline chloride 0.8, with vitamins A, D, E and K. After 10 days 2 rats had the choline replaced by methionine and 4 received no choline. Later, deuterium oxide was given in the drinking water for 3 weeks before the rats were killed.

The 4 rats receiving no choline derived from 24.4 to 34.3 per cent. of their labile methyl groups from labelled body water, but those receiving choline or methionine only 5.5 to 10.4 per cent. The appearance of deuterium in the labile methyl groups thus reflected the degree of new formation of these groups.—D. Duncan.

VITALE, J. J., DI GIORGIO, J., McGRATH, H., NAY, J. and HEGSTED, D. M. **Alcohol oxidation in relation to alcohol dosage and the effect of fasting.** *J. Biol. Chem.*, 1953, **204**, 257-264. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston.]

Ethanol-1-¹⁴C was injected into the peritoneum of rats and the rate of metabolism of ethanol was measured by estimating the ¹⁴CO₂ in the respired air. The rate of oxidation of ethanol was directly proportional to the amount administered up to about 2.5 to 3.0 g. per kg. bodyweight. At higher levels the rate declined. Fasting decreased the rate of oxidation of ethanol at the 2.4 g. level of administration, the extent of the decrease depending on the length of the fast. Fasting also decreased the ability of liver homogenates to oxidase ethanol.—W. Godden.

BING, R. J., SIEGEL, A., VITALE, A., BALBONI, F., SPARKS, E., TAESCHLER, M., KLAPPER, M. and EDWARDS, S. **Metabolic studies on the human**

Vol. 24, No. 2

heart in vivo. 1. **Studies on carbohydrate metabolism of the human heart.** *Amer. J. Med.*, 1953, **15**, 284-296. [Dept. Med., Med. Coll. Alabama, Birmingham.]

Blood was obtained from the coronary vein by direct intubation of the coronary sinus in 52 patients, and mixed venous blood was obtained from the pulmonary artery or the right ventricle. Nine patients were in cardiac failure, 3 with low output and 6 with thyrotoxicosis and high output.

In the non-failing heart, glucose consumption varied from 1.37 to 13.65 mg. per 100 g. heart muscle per min. and extraction rose with arterial glucose concentration to a maximum when the latter was about 110 mg. per 100 ml. Injection of a 10 per cent. glucose solution resulted in increasing glucose extraction by the myocardium regardless of the arterial glucose concentration.

In low or high output failure there were decreased ability of the heart to convert glucose or lactate energy to work, and increased uptakes. Spontaneous variations in arterial lactate concentration were related to lactate uptake by the heart. From 0.35 to 11.5 mg. lactate per 100 g. muscle per min. were used, but glucose seemed to be preferred. Pyruvate utilisation was small, up to 0.83 mg. per 100 g. muscle per min., and could not be definitely related to arterial pyruvate concentration. The total aerobic metabolism of glucose, lactate and pyruvate usually fell far short of the total O_2 consumption of the left ventricle, even with high arterial glucose concentration, and the heart appears to depend for its energy also on non-carbohydrate sources.—D. Duncan.

VILLEE, C. A. **The metabolism of human placenta *in vitro*.** *J. Biol. Chem.*, 1953, **205**, 113–123. [Dept. Biol. Chem., Harvard Med. Sch., Boston, Mass.]

From 30 placentae at term, and 33 of gestational age ranging from 6 to 37 weeks, the metabolism of macroscopically healthy slices was tested *in vitro*, beginning within 5 min. after vaginal or abdominal delivery. [It is not stated whether obstetrical abnormalities were associated with these placentae.] The slices were incubated at 37° C. in Warburg vessels, and glucose, pyruvate and lactate, labelled with ^{14}C , were added to the incubation medium. The technique for each experiment is described in detail.

The results are presented as scatter diagrams with a superimposed line [which is apparently the mean. The scatter of results about this line is wide, and there are no statistical data by which the validity of the means can be assessed.]

The dry weight : wet weight ratio rose throughout gestation from a mean of approximately 7.5 per cent. in early pregnancy to a mean of approximately 12.0 per cent. at term. The mean glycogen content per unit dry weight fell steeply until about mid-pregnancy, and then more gradually until term. The ability of the placenta to form gly-

cogen *in vitro* decreased with increasing gestational age, and was inhibited completely by omitting K from the incubating medium.

Oxygen utilisation per unit dry weight fell until about mid-pregnancy and then remained almost constant until term, and there appeared to be a small decrease in the mean ability to produce and use glucose and pyruvate and to produce lactate throughout pregnancy.

The placental slices were unable to metabolise glycerol, and it appeared that the placenta had no phosphorylating enzyme.

Insulin in the incubating medium was found to accelerate glucose utilisation, and both cortisone and aqueous adrenal cortical extracts decreased the use of oxygen and glucose.

Eight experiments were made on placentae from women with pre-eclamptic toxæmia; these did not differ significantly from "normal" placentae of comparable age. Two hydatidiform moles were found to use oxygen, glucose and pyruvate at lower rates than placentae of corresponding age.

It is concluded that with increasing gestational age there is a general decrease in the metabolic activity of the placenta.—F. E. Hytten.

BERTALANFFY, L. V. and PIROZYNSKI, W. J. **Tissue respiration, growth and basal metabolism.** *Biol. Bull.*, 1953, **105**, 240–256. [Dept. Biol., Fac. Med., Univ. Ottawa.]

For preliminary report see Abst. 3685, Vol. 21.

Tissues were obtained from rats maintained on Purina chow, but restricted to tap water for 12 to 18 hr. before being killed.

Q_{O_2} of heart, lung, kidney and brain showed no relation to body size, but diaphragm showed a significant decline in Q_{O_2} with increasing body-weight. The logarithmic curves of liver and thymus Q_{O_2} against bodyweight showed distinct breaks at 100 g. bodyweight, at the time when the relative growth rates of these organs change. Current theories on the decrease of total B.M.R. with growth are discussed.—D. Duncan.

BARTLETT, G. R. and MARLOW, A. A. **Erythrocyte carbohydrate metabolism. 1. The flow of C^{14} -glucose carbon into lactic acid, carbon dioxide, cell polymers, and carbohydrate intermediate pool. 2. Chromatographic isolation of monophosphoglycerate, diphosphoglycerate, and adenosine triphosphate and their metabolic turnover with glucose carbon.** *J. Lab. Clin. Med.*, 1953, **42**, 178–187; 188–192. [Scripps Metabol. Clin., La Jolla, Calif.]

1. Defibrinated human blood was incubated for 4 hr. at 38° C. with uniformly labelled ^{14}C glucose; the red blood cells were then separated and

N.A. and R., April 1954

washed with cold isotonic saline, the surface coat of leucocytes and fat particles being aspirated off and discarded. The cells were extracted with trichloroacetic acid, the extract was divided into 5 fractions and the radio-activity of their C was estimated. In the time allowed for incubation half of the lactic acid C formed was derived from radio-active glucose, the remainder coming from the unlabelled carbohydrate storage mixture in the cells. This in turn was replaced by ^{14}C from glucose. The insolubles from the trichloroacetic acid extraction had no significant activity, emphasising the red cell's inability to form protein or fat. Slightly less than 1 per cent. of the glucose C went to $^{14}\text{CO}_2$, and it was calculated that this was probably due to contaminating reticulocytes and leucocytes rather than to any real respiratory capacity of the mature red cell. The fractions of the extract were analysed for glucose, lactic acid, fructose, ribose, adenine, triose, total C, C derived from metabolic glucose, total P, inorganic P, and inorganic P hydrolysed at 10 min., 1 hr. and 3 hr. From these results an estimate was made of the amounts of the different phosphates, phosphoglyceride and diphosphopyridinenucleotide present.

2. The barium-insoluble fraction of the trichloroacetic acid extract referred to above was separated by ion exchange chromatography into its C constituents. The results from the measurement of radioactivity of the individual constituents indicate a high turnover rate with glucose C for diglycerophosphate and to a lesser extent for monoglycerophosphate, none for adenine and possibly a trace for ribose-5-phosphate.

RENOLD, A. E., TENG, C. T., NESBETT, F. B. and HASTINGS, A. B. **Studies on carbohydrate metabolism in rat liver slices. 2. The effect of fasting and of hormonal deficiencies.** *J. Biol. Chem.*, 1953, **204**, 533-546. [Dept. Biol. Chem., Harvard Med. Sch., Boston, Mass.]

For part 1 see Abst. 954, Vol. 22.

Utilisation of glucose and pyruvate was studied with liver slices from rats, using ^{14}C -glucose uniformly labelled in all C atoms, and ^{14}C -pyruvate labelled in the α -carbon.

Liver slices from rats fasted for 18 to 24 hr. deposited in the medium 65 per cent. less glycogen from glucose and 35 per cent. less from pyruvate than livers from rats fed to appetite. Livers from alloxan-diabetic rats showed a consistent net glycogen decrease during incubation and deposited less total glycogen than those of normal controls, and of this glycogen 3 glucose units were obtained from pyruvate for every one from glucose, a reversal of the normal ratio. There was much more glucose produced, 2 or 3 times the normal amount, accounted for by glycogen breakdown, conversion of

pyruvate to glucose, and increased glucose production from unidentified sources. Similar results were obtained from livers of rats after removal of the pancreas. Adrenal removal did not alter the normal metabolism and when it was imposed on alloxan diabetes net glycogen breakdown decreased slightly and glucose output considerably. Pituitary removal had effects similar to those of adrenal removal.

After fasting for 18 to 24 hr. the livers of alloxan-diabetic rats retained on the average $76.7 \mu\text{M}$ glycogen per g. tissue, whereas in normal animals liver glycogen after such a fast is negligible.

D. Duncan.

MEDES, G., SPIRITES, M. A. and WEINHOUSE, S. **The estimation of fatty acid synthesis in rat liver slices.** *J. Biol. Chem.*, 1953, **205**, 401-408. [Lankenau Hosp. Res. Inst., Philadelphia, Pa.]

Male rats previously fed on a stock diet were starved for 24 to 48 hr. before being fed for 1 day on a diet containing 55 per cent. sucrose and 15 per cent. each of casein, glucose and milk powder. Liver slices were then incubated in the presence of Na acetate labelled with ^{14}C in the methyl or carboxyl group, lactate labelled with ^{14}C in the α -carbon, or ^{14}C glucose labelled uniformly in all the carbon atoms; the incubations were at 38°C . in oxygen for 4 hr. The radio-activity of respired CO_2 , fatty acids, acetoacetate and cholesterol was then estimated.

The rate of fatty acid formation was estimated by comparing the specific activities of the acetoacetate and fatty acids. Incorporation of ^{14}C from acetate, lactate and glucose into CO_2 , acetoacetate, fatty acids and cholesterol was proportional to substrate concentration over a wide concentration range. It was calculated that from 4 to 22 days are required for replacement of half the liver fatty acids, as compared with 1 to 2 days reported by Pihl *et al.* (Abst. 2305, Vol. 20) from experiments on living rats.—G. A. Garton.

2172

CHEN, R. W., CHAPMAN, D. D. and CHAIKOFF, I. L. **Acetoacetate conversion to fatty acids in liver: the role of insulin and the nutritional state of the animal.** *J. Biol. Chem.*, 1953, **205**, 383-393. [Dept. Physiol., Sch. Med., Univ. California, Berkeley.]

Liver slices were prepared from rats which had been fed on a stock diet, some of which had then been fasted, and from animals rendered diabetic with alloxan, some of which had been treated with insulin. The slices were incubated with acetoacetate labelled with ^{14}C in the carbonyl C atom. The ^{14}C content of the resulting CO_2 and fatty acids was estimated.

Liver slices from animals kept on the stock diet readily incorporated the labelled C atom of acetoacetate into long-chain fatty acids. This incorporation did not occur in the liver tissue of fasted or diabetic rats, but did take place when the latter had been given insulin injections. Possible mechanisms for the formation of fatty acids from acetoacetate are discussed.—G. A. Garton.

GEYER, R. P., MEADOWS, M. F., MARSHALL, L. D. and GONGAWARE, M. S. **The influence of sodium, potassium, and lithium on fatty acid metabolism.** *J. Biol. Chem.*, 1953, **205**, 81–85. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

Liver and kidney slices obtained from male rats of Wistar strain which had been maintained on a stock diet were incubated at 38° C. for 1 hr. under oxygen with pentanoic acid-1-¹⁴C or octanoic acid-1-¹⁴C as substrate. The incubation media contained 9 parts of NaCl and 1 part of sodium phosphate-HCl buffer; isotonic KCl or LiCl solutions were substituted for the NaCl solution to give media containing 15 or 77 m.equiv. K or Li per litre. The radio-active CO₂ and acetoacetate produced were estimated.

In liver slices, both K and Li increased breakdown of octanoate, which was reflected mainly in acetoacetate production. The ratio of acetoacetate to ¹⁴CO₂ was below 1 in an all-Na buffer medium, but above 3 when K or Li was present. Potassium caused an increase in both acetate and ¹⁴CO₂ produced from pentanoate. Octanoate metabolism by kidney slices was increased by K, but not by Li.—G. A. Garton.

2174

ARTOM, C. **Role of choline in the oxidation of fatty acids by the liver.** *J. Biol. Chem.*, 1953, **205**, 101–111. [Dept. Biochem., Bowman Gray Sch. Med., Wake Forest Coll., Winston-Salem, N. Carolina.]

Male albino rats were maintained on stock diet containing 25 per cent. protein and 5 per cent. fat or a diet containing 5 per cent. fat and 5 per cent. casein. The latter diet was supplemented with choline chloride or guanidoacetic acid as required. Liver slices, homogenates or particle suspensions were prepared and incubated with ¹⁴C-labelled stearate or palmitate; the radio-activity of the CO₂ and acetoacetate evolved during the incubation was estimated.

Liver preparations from animals on the low-protein diet produced less ¹⁴CO₂ than preparations from animals on stock diet. Choline added to the low-protein diet generally restored the ability of the liver to produce ¹⁴CO₂ at a high rate. The amounts of labelled acetoacetate formed were pro-

portional to those of ¹⁴CO₂. Irrespective of previous dietary history, the addition to liver preparations of choline, betaine aldehyde, betaine or phosphorylcholine did not stimulate the production of ¹⁴CO₂.

It is suggested that the lipotropic effect of choline may be due to a large extent to increase of fatty acid oxidation in the liver.—G. A. Garton.

REICHARD, P. and LAGERKVIST, U. **The biogenesis of orotic acid in liver slices.** *Acta chem. scand.*, 1953, **7**, 1207–1217. [Biochem. Dept., Karolinska Inst., Stockholm.]

Experiments *in vitro*, the methods for which are fully described, were of two kinds. In the first a labelled substance considered likely to be a precursor of orotic acid, and unlabelled orotic acid, were incubated with the slices; orotic acid was then isolated from the medium and, after partial degradation, the distribution of the isotope within its molecule was deduced. In the second, incubation was with the supposed precursor or with orotic acid, both unlabelled, but in presence of ¹⁵NH₄Cl, after which the distribution of ¹⁵N in the orotic acid was studied.

The evidence was that N₃ plus C₄, C₅, C₆ and C₇ of orotic acid were derived from aspartic acid and that L-ureidosuccinic acid was a normal intermediate in the formation of orotic acid in liver slices.

[Effect of glucose and glycogen on normal cartilage ossification *in vitro*.] *C.R. Acad. Sci.*, 1953, **237**, 1287-1289.

See Title 720, Vol. 21 and Abst. 2047, Vol. 23.

Sections of ossifiable cartilage from sheep embryos were placed for 20 hr. at 37° C. in mineralising solutions containing Ca, P as adenosinetriphosphate (ATP) or orthophosphate, and glucose or glycogen.

The cartilage utilised glucose, for the most part anaerobically, with little formation of citrate. The presence of glucose greatly diminished mineralisation by ATP. Utilisation of glycogen was slight and did not affect mineralisation. Inhibitors of glucose breakdown, monoiodoacetic acid or NaF, increased mineralisation, but inhibitors of the aerobic phase, cyanide, malonate and fluoracetate, were without effect. The results demonstrate the antagonism between glucose breakdown and mineralisation by ATP.—D. Duncan.

MARKS, P. A., HIATT, H. H. and SHORR, E. **Factors influencing deposition of calcium and strontium in cartilage *in vitro*.**

HIATT, H. H., MARKS, P. A. and SHORR, E. **Effects of inhibitors on calcium deposition in cartilage *in vitro*.** *J. Biol. Chem.*, 1953, **204**, 175-185; 187-195. [Russell Sage Inst. Pathol., Cornell Univ. Dept. Med., New York.]

Sections were prepared from the proximal end of the tibia and distal end of the femur of rachitic rats for tests of mineralisation *in vitro*.

Sr and Ca were deposited in a similar manner, but higher concentrations of Sr and phosphate than of Ca and phosphate were required. Phloridzin and iodoacetamide inhibited deposition of Ca and Sr, but KCN did not. Sections were stained for glycogen before incubation, and calcification took place in regions which originally contained glycogen. When sections were treated with amylase to hydrolyse glycogen, there was hardly any calcification during subsequent incubation in solutions containing Ca and phosphate.

In similar experiments calcification was reduced by temperatures above and below 37° C.

The deposition of Ca was not inhibited by 2:4-dinitrophenol, azide, malonate, or anaerobic conditions, which indicated that oxidative processes were not essential in endochondral calcification.

In tests with inhibitors of alkaline phosphatase, it was found that the enzyme was required only when P was present as phosphoric esters.—R. Hill.

2180

BOSTRÖM, H. and MÄNSSON, B. **Factors influencing the exchange of the sulphate group of the chondroitin sulphuric acid of cartilage *in vitro*.**

Vol. 24, No. 2

Ark. Kemi, 1953, **6**, 23-37. [Dept. Chem., Karolinska Inst., Stockholm.]

A standard method was devised of incubating costal cartilage from calves 1 to 3 days old for 30 min. with Krebs Ringer bicarbonate solution containing Na₂SO₄ labelled with ³⁵S. Thereafter the chondroitin sulphuric acid was isolated by the authors' procedure (Abst. 1512, Vol. 24) and its radio-activity was estimated. The effects of a number of changes in conditions were then studied.

Homogenisation of the cartilage or heating to between 43° and 47° C. before incubation, or raising the temperature to 50° C. during incubation, almost completely inhibited incorporation of ³⁵S; aeration with N during incubation diminished it to about 36 per cent. of the standard. Rapid freezing followed by thawing, or keeping of the cartilage for 4 days after collection, also destroyed the power to take up ³⁵S. Cartilage from 2- and 12-year-old animals had activities 57 and 26 per cent., respectively, of that of cartilage from suckling calves. The effects of 28 enzyme inhibitors were studied; many had positive effects and the most powerful were those known to react with SH groups in proteins. Cortisone also was strongly inhibitory.—D. Harvey.

2181

BOSTRÖM, H. and ODEBLAD, E. **The influence of cortisone upon the sulphate exchange of chondroitin sulphuric acid.** *Ark. Kemi*, 1953, **6**, 39-42. [Dept. Chem., Karolinska Inst., Stockholm.]

In experiments with adult rats 1 mg. cortisone acetate per 100 g. bodyweight was given daily and on the fifth day they and control animals were injected with Na₂SO₄ labelled with ³⁵S; 48 hr. later they were killed. Chondroitin sulphuric acid was prepared (Abst. 1512, Vol. 24) from the costal cartilage and its radio-activity was measured; autoradiographs were obtained from samples of skin. Experiments *in vitro* were with costal cartilage from young calves incubated in Krebs Ringer bicarbonate solution with different amounts of cortisone alcohol.

The evidence from the experiments *in vivo* was of a reduction of radio-activity in the treated group to 60 per cent. of that of the control and from the work *in vitro* of about 35 per cent. inhibition when the concentration of cortisone alcohol was 10 mg. per cent.—D. Harvey.

ZIRM, K. L., PONGRATZ, A. and POLESOFKY, W. **Über die Bildung von Assoziationskomplexen des Chlorophyllins mit Eiweisskörpern. [Formation of association complexes by chlorophyllin with proteins.]** *Biochem. Ztschr.*, 1953,

324, 536-543. [Forsch. Lab., Lannacher Heilmittel G.m.b.H., Lannach, Styria.]

When freed from lipoprotein, water-soluble Mg chlorophyllin is capable of forming with proteins a complex which shows properties similar to those of the natural chromo-lipoprotein complex. The central Mg atom can be replaced by other metals, and it has been found that Co, Ni, Zn and Cu chlorophyllins behave similarly in forming protein complexes. It is believed that this power of combining with protein and its decomposition products is of special significance in connection with the tissue-positive ("gewebspositive") and deodorising properties of the natural substance. The therapeutic significance of the complexes depends on the nature of the central atom. See also Abst. 2140, Vol. 24.—M. B. Richards.

GROWTH AND METABOLISM OF TUMOUR CELLS

2183

EULER, H. v. Biochemische Vorgänge bei der Bildung und beim Wachstum von Tumoren. [Biochemical events in the formation and growth of tumours.] *Deutsch. med. Wochenschr.*, 1953, **78**, 1755-1758. [Vitamin Inst., Univ. Stockholm.]

This is a review which discusses briefly the carcinogenic action of butter yellow, the breakdown of that substance by demethylation first to the monomethyl compound, still carcinogenic, and finally to the harmless aminoazobenzol. Riboflavin is thought to have some protective effect which is ascribed to its action in the formation of precursors of haem and in tryptophan metabolism.

HAMMOND, W. H. Physique and development of boys and girls from different types of school. *Brit. J. Prev. Social Med.*, 1953, **7**, 231-239. [Minist. Health, London.]

As part of a wider post-war study, weights, heights and other body measurements were ascertained for boys and girls from 5 to 18 years in independent schools (group A) and up to 14 or 15 years in council schools in the best (group B) and worst areas (group C) of several industrial towns. There were about 1430 children from

independent and 1495 from council schools. They were measured by a team of 3, each of whom was responsible for particular measurements throughout. The means are tabulated for groups A and C and the results for these are compared and shown graphically. The means for group B, the standard deviations, and details of the techniques, are obtainable from the author.

Body measurements could be divided into 2 groups: those which showed a steady increase with age, namely, height, arm and leg length, length and breadth of hand and foot, and inter-acromial, interspinous and ankle breadth; and those which showed a pubertal spurt, more especially in boys, namely, weight, sitting height, girths of trunk, knee, arm and wrist, and intertrochanteric breadth. Group A children surpassed group C in height and most length measurements, being about 2 years' growth ahead; for girth measurements the differences were much less. The inter-relationships of the measurements are discussed. The ratio sitting height: leg length and other indices of maturity indicated that group A were also about 2 years ahead in "shape". It is suggested that "the different mature physiques of the social groups are due to these differences in the rate of development rather than to specifically social differences".—W. M. Deans.

KEMSLEY, W. F. F. **Changes in body weight from 1943 to 1950.** *Ann. Eugenics*, 1953, **18**, 22-42.

The paper is intended to show the weight changes which occurred in groups of British adults over the period 1943 to 1950 and to aid the planning of any future inquiry by providing information on the variation of individuals over time. A description of the samples used is given in an earlier paper by the same author, dealing exclusively with the cross-sectional survey in 1943 (Abst. 4119, Vol. 20).

The relative merits of a series of consecutive independent samples and a longitudinal study are considered, as well as the disadvantages of both systems.

The results obtained from a small group weighed throughout the survey are presented, interpreted and compared with those obtained in 1943. Both sets of data are similar, apart from the greater age of the smaller set and the fact that they show a greater annual increase in mean weight.

Annual comparisons are used to investigate annual and quarterly weight changes.

Finally, the variances of weight changes are examined. The correlation between different weighings of the same individual is high even when the weighings are as far as 7 years apart. From this it can be concluded that longitudinal surveys are more efficient than cross-sectional inquiries in estimating weight changes over time, requiring approximately one-fifteenth of the number of subjects for comparable accuracy, provided sufficient numbers of the original sample remain available. Although weight is distributed log-normally, the distribution of weight changes tends to normality as the interval between weighings becomes longer.—A. W. Boyne.

2189

BOTKIN, M. P. and WHATLEY, J. A. (Jr.) **Repeatability of production in range beef cows.** *J. Animal Sci.*, 1953, **12**, 552-560. [Dept. Animal Husb., Oklahoma Agric. Exp. Stat., Stillwater.]

Birth and weaning weights were recorded at Stillwater, Oklahoma between 1944 and 1951, where 151 range Hereford cows produced 620 calves and weaned 603, and at Fort Reno Experiment Station in 1950 and 1951, where 49 cows produced and weaned 98 calves. After elaborate corrections for sex of calf, age of dam and year, correlation between records for first and second calf were worked out.

It is concluded that in the selection of beef cows the weaning weights of their first calves can be taken as an indication of future performance.

SCHWARTZ, N. B. **Relationship between body weight and gastrocnemius-soleus muscle weight in growing rats.** *Growth*, 1953, **17**, 123-126. [Dept. Physiol., Northwestern Univ. Med. Sch., Chicago, Ill.]

The gastrocnemius-soleus muscle on one or both sides was removed by dissection under Nembutal or Barbitol anaesthesia from 95 male Sprague-Dawley rats aged from 21 to 110 days and weighing from 30 to 420 g. The muscle was weighed, dried for 24 hr. at 100° C. and re-weighed.

Dry weight was linearly related to wet weight except at very low muscle weights. There was no significant difference between right and left muscles. The wet weight of the first muscle removed was slightly but significantly greater than that of the second; the former was used. Contrary to the usual assumption, the relation between muscle weight and bodyweight was not linear over a wide range of bodyweight, but was expressed by the equation :

Muscle weight (wet) in g. =

$$1.77 (\text{Bodyweight in g.})^{1.24}.$$

MUKHERJEE, D. P., ROY, A. and BHATTACHARYA, P. **The effect of feeding thyroprotein on semen quality and on some physiological conditions of goats. 1. Effect on reaction time and semen characteristics.**

ROY, A., MUKHERJEE, D. P., LUKTUK, S. N. and BHATTACHARYA, P. **2. Effect on sperm nutrient and its utilisation.**

MUKHERJEE, D. P., JAWA, S. S. and BHATTACHARYA, P. **3. Effect on pulse rate, rate of respiration, body temperature and body weights.** *Indian J. Vet. Sci.*, 1953, **23**, 1-7; 9-14; 15-24. [Animal Genetics Sect., Indian Vet. Res. Inst., Izatnagar.]

1. Thyroprotein, 1 g. daily, was given by mouth to 7 male goats. A comparable control group received no thyroprotein. The experiment was made between May and August, when environmental temperatures were high. Semen samples were taken twice weekly from all animals. The degree of sex vigour was also estimated by noting the time interval between release of the goat and ejaculation ("reaction time").

Thyroprotein had no effect on sperm motility, number of spermatozoa in the ejaculate or percentage abnormal sperm. The reaction time was unaffected. There was a significant decrease in semen volume and a corresponding increase in sperm concentration in goats given thyroprotein.

2. Thyroprotein had no effect on the methylene blue reduction time in the semen samples taken during the above experiment. The initial fructose content decreased and the rate of fructolysis increased during thyroprotein feeding. There was a high correlation between sperm concentration and rate of fructolysis.

3. Statistical analysis of data collected during the above experiment showed that thyroprotein raised pulse and respiration rates and body temperature and decreased bodyweight.

Pulse rates of control and treated animals increased as air temperatures rose. The control group reacted to a greater degree than the treated animals. An increase of relative humidity tended to decrease pulse rates in both groups when temperature and rainfall were constant. Respiration rates of the treated animals increased with increasing air temperature. Rainfall had no effect on pulse or respiration rate. Body temperatures were unaffected by changes in atmospheric temperature, humidity or rainfall.—J. N. Aitken.

2196

UNDERWOOD, E. J., SHIER, F. L. and PETERSON, J. E. **The effects of prolonged injections of stilboestrol on the ewe.** *Austral. Vet. J.*, 206-211. [Inst. Agric., Univ. W. Australia.]

Mature Merino ewes were given intramuscular injections of stilboestrol in oil daily for 6 months including the normal anoestral period when no progesterone is produced to protect the uterus from the effects of oestrogens. In the first experiment the doses were 1, 2, 4, 8 or 16 mg., and in the second 0.11, 0.33 or 1 mg. daily.

All treated animals in the first experiment showed mammary development during treatment. Raddled entire rams were introduced to the flock, and mating records indicated that the treatment had no effect on the incidence of oestrus, but at all dose levels almost complete infertility resulted. Observations were continued for 3 breeding seasons, and the infertility persisted. Reproduction in control ewes was normal. In the second experiment the permanence of the infertility has not yet been confirmed, but it is thought that even the lower levels of stilboestrol will have permanent effect. Post-mortem findings, which are described, were similar to those in ewes rendered infertile by grazing on subterranean clover pastures.

DEWAR, A. D. **Total metabolism of the mouse after pseudo-parturition and parturition.** *Quart. J. Exp. Physiol.*, 1953, **38**, 263-294. [Dept. Physiol., Univ. Edinburgh.]

Pseudoparturition was induced by crushing the foetuses on the 14th or 15th day of gestation, the day of delivery of the placentae being ascertained by daily palpation. Consecutive 24-hr. balances of water, carbohydrate, fat and protein and estimated energy expenditure were studied in 7 of these mice, in 3 after normal parturition and in non-pregnant controls, and B.M.R. was studied in newborn litters.

Weight losses after parturition or pseudo-parturition were due mostly to water loss which was not due to simple diuresis, as excretion usually fell, but to decreased intake uncompensated by the decrease in excretion. The water

N.A. and R., April 1954

loss was accompanied by negative Na balance and represented the termination of a water-retaining phase, probably involving mainly extracellular water and associated with the presence of placentae. Decreased food intake in the 3 or 4 days after parturition accounted for a further small loss of weight.

Some loss of N followed parturition or pseudoparturition. No change in fat or carbohydrate metabolism appeared. A decline in energy expenditure occurred in the 3 or 4 days after pseudoparturition, and the B.M.R. was increased before pseudoparturition. The B.M.R. per unit of weight in newborn mice was only about two-thirds that of the mother, and it is thought that an increase in maternal B.M.R. at the end of pregnancy would be masked by the low B.M.R. of the foetuses.

D. Duncan.

2198

NELSON, M. M. and EVANS, H. M. **Relation of dietary protein levels to reproduction in the rat.** *J. Nutrition*, 1953, **51**, 71-84. [Inst. Exp. Biol., Univ. California, Berkeley.]

Groups of 10 normal adult rats were given from the day of mating purified diets of casein, sucrose, hydrogenated cottonseed oil, salts and essential vitamins. Protein contents of 2.5, 5, 10, 15, 20 and 25 per cent. and a protein-free diet were obtained by interchanging casein and sucrose.

Maternal weight gain during gestation decreased with decreasing protein content until with 2.5 per cent. protein or none there was loss of weight. At protein levels above 5 per cent. there was no resorption of litters and young of average size and number were produced. At 5 per cent. protein there was 30 per cent. resorption of implanted ova and the young born were below average weight. With 2.5 per cent. protein or none 90 to 100 per cent. of foetuses were resorbed and the average weight of young born was very low.

Additional groups were given the diets containing 5 and 2.5 per cent. protein or none with the crystalline vitamin supplement doubled and vitamin B₁₂ added. The additional vitamins reduced the percentage of resorptions in the 5 and 2.5 per cent. protein groups but not in the protein-free group.

In a paired feeding trial rats on the protein-free diet consumed 9.2 g. food daily, lost weight during gestation and resorbed 89 per cent. of ova implanted and the young born were small. Pair-fed animals on a 20 per cent. protein diet gained weight and resorbed 11 per cent. of ova implanted and the young were below average weight. When the protein content of the diet of pair-fed controls was increased to 30 per cent. there was 100 per cent. development of ova implanted and the young were of normal birthweight.

The effects of giving a protein-free diet from

before gestation, from 7 days after breeding or for transitory periods during gestation were studied. The incidence of resorption of litters in rats on protein-free diet was much reduced if implantation occurred before the reduction of protein intake.

No young rat with a macroscopic congenital abnormality was observed in the low-protein or protein-free groups.—F. C. Aitken.

2199

WILSON, J. G. **Influence of severe hemorrhagic anemia during pregnancy on development of the offspring in the rat.** *Proc. Soc. Exp. Biol. Med.*, 1953, **84**, 66-69. [Dept. Anat., Coll. Med., Univ. Cincinnati, Ohio.]

Pregnant rats were made severely anaemic by being bled on 3 successive days beginning on the 7th day in 31, on the 9th day in 40, on the 11th in 37 and on the 13th in 25. This frequently caused maternal death or resorption of the litter. Surviving litters were normal except when bleeding was begun on the 9th day, when there was malformation in 2.6 per cent. of the young, retardation of growth in 4 of 13 litters and a slightly higher than normal rate of intra-uterine resorption in litters reaching term. It is suggested that maternal haemorrhagic anaemia is not a great danger to the offspring of surviving litters.—F. C. Aitken.

2200

ILLINGWORTH, R. S. and KILPATRICK, B. (with SCOTT, J. F.) **Lactation and fluid intake.** *Lancet*, 1953, **265**, 1175-1177. [Dept. Child Health, Univ. Sheffield.]

Criteria of successful lactation were gain in weight of baby by the 5th and 9th day, results of test feeds on the 8th day and incidence of full breast feeding on discharge from hospital and at 1 month of age.

The average amount of fluid drunk daily by 106 mothers given no direction about fluid intake was 69.1 oz.; that of 104 mothers advised to drink 6 pints daily was 107.5 oz. No positive correlation was found between any of the criteria and fluid intake. There was a significant negative correlation between fluid intake and milk produced at test feeds. Lactating women should not be persuaded to drink large quantities, but should be allowed to satisfy their own desire for fluid.

FLYNN, F. V., HARPER, C. and DE MAYO, P. **Lactosuria and glycosuria in pregnancy and the puerperium.** *Lancet*, 1953, **265**, 698-704. [Dept. Clin. Pathol., University Coll. Hosp., London.]

Single samples of urine from 240 non-pregnant women and 132 men, 2373 from 240 pregnant women and 657 post-partum specimens were

tested for reducing sugars by the Benedict method and for lactose and glucose by paper chromatography.

Positive reduction tests occurred in pregnancy about $2\frac{1}{2}$ times and *post partum* about 3 times as often as in the controls. The percentages of urine samples containing lactose were: non-pregnant women 9.6, men 8.3, pregnant women 50.9, women after delivery 86.2. The corresponding percentages of glycosuria were 14.2, 15.9, 24.0, 0.9. Antenatal lactosuria increased in incidence as pregnancy progressed, was found more often in the afternoon and more commonly in primigravidae than in multigravidae. Antenatal glycosuria was found more often in the afternoon and more frequently in older than younger women.

A new spray reagent is described for use in paper chromatography of sugars.—F. C. Aitken.

OWEN, J. B. Milk yield of hill ewes. *Nature*, 1953, **172**, 636–637. [Sch. Agric., Univ. Coll. N. Wales, Bangor.]

By the use of a harness, designed to prevent the lamb reaching the ewe's udder but easy to manipulate at suckling time, mean daily milk yields of 32 randomly selected hill ewes with single lambs, grazing on "inbye" land at 1000 ft. above sea level, was found to be 31.79 ± 6.04 oz. over a 6-week period. Pedigree ewes over a shorter period averaged 47 oz. There was a high correlation, $r = +0.79$, between the milk yield of the ewe and the growth of the lamb during the first month and significant correlations between the milk yield of the ewe and the birthweight of the lamb, $r = +0.51$, and the weight of the ewe at tupping, $r = +0.36$.—W. Godden.

FRENCH, C. E., INGRAM, R. H., URAM, J. A., BARRON, G. P. and SWIFT, R. W. The influence of dietary fat and carbohydrate on growth and longevity in rats. *J. Nutrition*, 1953, **51**, 329–339. [Dept. Animal Nutrit., Pennsylvania State Coll., State College.]

Male and female rats on a diet containing 22.7 per cent. fat grew fully as rapidly as those on a high-carbohydrate diet with only 3.4 per cent. fat, although their energy intakes were less by 4.8 and 5.7 per cent., respectively, than those of males and females on the latter diet. No seasonal variation in food consumption was found. Longevity decreased considerably in male rats and less, but significantly, in females on the high-fat diet. Although males on this diet had a significantly greater liver fat content than males on the carbohydrate diet, no evidence of abnormality in liver or kidney was revealed histologically, and the frequency of diseases or abnormalities was not greater in the high-fat group.—M. B. Richards.

EXPERIMENTAL STUDIES OF IMMUNITY AND MICRO-ORGANISMS

2207

DESOWITZ, R. S. and WATSON, H. J. C. Studies on *Trypanosoma vivax*. 7. The course of infection of an unsupplemented line in white rats and the influence upon it of a diet of cow's milk and vitamins. *Ann. Trop. Med. Parasitol.*, 1953, **47**, 258–260. [Sect. Protozool., W.

African Inst. Trypanosomiasis Res., Vom, N. Nigeria.]

[Earlier papers in the series were not nutritional.]

Rats receiving cow's milk, with or without added vitamins, were infected by inoculation with blood containing *Trypanosoma vivax*. The course of the infection was similar to that in controls on stock

N.A. and R., April 1954

diet. Vitamin B₁, vitamin B₆ and Ca pantothenate were without effect. The strain used, although originally requiring supplementary inoculation of sheep serum, has developed the ability to produce virulent and usually fatal infections in rats.

2208

KEPPIE, A. A. N. **Modified course of *T. congolense* infection in mice given diets with milk casein.** *Brit. Med. J.*, 1953, ii, 853-857. [Dept. Bacteriol., Univ. Glasgow.]

Groups of 20 mice received stock diet (Rowett Institute diet No. 86), synthetic diets containing 10, 20 or 30 per cent. casein, or bread, milk and oats, for 2 or 3 weeks before they were inoculated with *Trypanosoma congolense* (Busimbi strain). On all the casein diets the development of the parasites was delayed or prevented, though it was acute on both natural diets. Since the bread, milk and oats diet did not prevent growth of the parasite, it is thought that the casein diets lacked some nutrient required by it.—D. Duncan.

[Effect of a milk diet on infection with *Plasmodium berghei*, *Plasmodium vinckei* and *Babesia rodhaini* in mice.] *Ann. Soc. belg. Méd. trop.*, 1953, 33, 245-257. [Inst. Méd. Trop. Prince Léopold, Antwerp.]

To test the resistance to *Plasmodium vinckei*, an injection of blood containing about 4 million parasites was made into the peritoneum of 4 adult and 5 weanling mice on Maeagraith's milk diet (Abst. 4848, Vol. 23) enriched with vitamins B₁ and B₆, and of 3 adult and 2 young mice on stock diet. None of the mice on the milk diet developed a fatal infection; for the first few days a small number of parasites appeared in the blood, but they disappeared rapidly, except in one weanling mouse in which a heavy infection had developed by the 5th day; it then cleared up but the animal developed a chronic infection when transferred to stock diet.

In experiments with *Plasmodium berghei*, 2 strains were used which usually killed mice in from 12 to 30 days; 2 young and 2 mature mice having the milk diet were infected with one or other of the strains; one mouse was immune but the other 3 died, though they survived a little longer than mice on stock diet.

For the final experiment a highly lethal strain of *Babesia rodhaini*, really a species of *Nuttalia*, was used. The milk diet conferred no immunity and all the animals died, all but one with haematuria.

ADAM, K. M. G. **In vivo observations on the ciliate protozoa inhabiting the large intestine of the horse.** *J. Gen. Microbiol.*, 1953, 9, 376-384. [Dept. Biol., Royal (Dick) Vet. Coll., Edinburgh.]

Pony A had fistulae into the caecum and ventral colon; pony B had fistulae into the caecum and into the ventral and the dorsal colon. Pony A was fed for periods of 3 weeks on the following succession of diets: (1) grass only, (2) grass plus 2 lb. oats daily, (3) hay only, (4) hay plus 2 lb. oats daily. Pony B received grass only for 4 weeks and hay only for a further 4 weeks. Total and differential counts of ciliate protozoa were made in the formalised gut samples by methods developed by the author (*Parasitology*, 1951, 41, 301).

The ponies had different distributions of types of protozoa in their intestines and the effects of different diets on these distributions were not the same. Moreover, wide variations in the daily counts made it difficult to distinguish changes due to diet in the numbers of ciliates. In A, the concentration of ciliates in the caecum showed no significant change until hay and oats were given, when the count fell. In the ventral colon grass with oats caused an increase in the total count, and a further increase resulted from hay alone. In pony B, no change in the total count was found in the caecum or dorsal colon when hay replaced grass, but in the ventral colon a slight fall ($P < 0.05$) in the total count was recorded. Differential counts of protozoal types in the caecum and colon are described and discussed.

Ciliates from the ventral colon of pony A were successfully transmitted to the ventral colon of pony B, in an attempt to establish the more varied fauna of A in B and to follow the effects of this on the distribution of existing types in the colon of B. Two types of *Cycloposthium* were established by introducing ventral colon contents from A into the stomach of B. On the 10th day after transfer *C. edentatum* formed less than 1 per

cent. of the population of the ventral colon of B, but by the 14th day it formed 26 per cent. *C. dentiferum* took 6 weeks to become as numerous as *C. edentatum*. Thereafter the numbers of the two species remained similar. Direct introduction of ventral colon contents of A into the ventral colon of B, through the fistula, established in B all the types found in A, but the distribution of types never became similar. The colour of the contents of the colon of B became similar to that of A. The distribution of types in the caecum of B was not affected by the changes in the fauna of the ventral colon, but numbers in the dorsal colon increased. In the ventral colon itself total counts rose sixfold after the introduction of the two *Cycloposthium* species, and a further significant rise was noted after the establishment of all the species from A.

Conjugation, which had formerly been seen only in *Blepharocorys* spp. and *Charonantes equi*, was seen after transmission of ciliates in a few pairs of *Cycloposthium bipalinatedum* and once in *C. edentatum*.—M. J. Masson.

HEALD, P. J., KROGH, N., MANN, S. O., APPLEBY, J. C., MASSON, F. M. and OXFORD, A. E. **A method for direct viable counts of the facultatively anaerobic microflora in the rumen of a sheep maintained on a hay diet.** *J. Gen. Microbiol.*, 1953, **9**, 207–215. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

The nutrient medium contained, in each 12 ml. deep culture bottle: 5 per cent. casein hydrolysate 2 ml., 0.5 per cent. tryptophan solution 0.5 ml., 1.5 per cent. sugar solution 1 ml., 2 per cent. agar dissolved in cleared and buffered rumen liquor 8.5 ml. The rumen liquor was obtained by centrifuging contents from hay-fed sheep, followed by Seitz filtration, and was buffered with phosphates. A series of carbohydrates was studied.

Crude wet rumen contents of a sheep fed only on hay were estimated to contain a population of 10^8 viable facultatively anaerobic bacteria per g., capable of fermenting soluble carbohydrates, including glucose, maltose, cellobiose and salicin. The importance of this facultatively anaerobic population may be considerable.—D. Duncan.

2214

MACPHERSON, M. J. **Isolation and identification of amylolytic streptococci from the rumen of the sheep.** *J. Pathol. Bacteriol.*, 1953, **66**, 95–102. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Samples were taken from the rumen of sheep on different diets. Twenty-five strains of amylolytic streptococci were isolated on yeast-starch-

agar plates and 12 were studied in detail. In fermentation reactions they were found to resemble *Streptococcus bovis* and the coccus RO-6TBR isolated from the rumen by Gall and Huhtanen (Abst. 2463, Vol. 21).

In Lancefield grouping tests the reactions of the rumen strains were weaker and slower to develop than those of *Str. bovis* or *Str. faecalis*. Supernatant fluid of a 10-hr. culture of a rumen streptococcus gave a strong precipitin reaction with homologous antiserum in dilutions up to 1 in 128 of the antigen, which appeared completely soluble and had the same precipitin reactions as formamide extracts of whole cells. Cells washed 3 times in saline before agglutination tests gave agglutination titres 20 times that of unwashed cells.

The Neufeld capsule swelling reaction was observed with antisera from rumen strains. Strains 1 and 2 gave a positive reaction to antisera 1 and 2 and a negative reaction to antiserum 3. Strain 3 gave a positive reaction with antiserum 3 only. *Str. bovis* and *Str. faecalis* were negative to all 3 antisera of rumen strains. Rumen contents did not interfere with the reaction. A positive reaction of capsules of rumen streptococci in whole rumen contents was demonstrated when antisera of the isolated strains were mixed with the rumen contents.—M. J. Masson.

HUDMAN, D. B. and KUNKEL, H. O. (with HOOD, B. J.) **Rumen microorganisms. Factors influencing protein synthesis by microorganisms in vitro.** *J. Agric. Food Chem.*, 1953, **1**, 1060–1062. [Dept. Biochem., Texas Agric. and Mech. Coll. System, College Station.]

Inocula of rumen liquor from sheep with a fistula fed on alfalfa hay were added to a saline medium containing glucose and powdered cellulose, the volume was made up to 333 ml. and the mixture was incubated at 39° C. The pH was adjusted initially and at 3-hr. intervals to between 6.5 and 6.6. The protein of samples drawn every 3 hr. was precipitated by tungstic acid and N was estimated in the washed precipitate.

Protein synthesis increased when urea or ammonium citrate was added; increasing the concentration of urea from 0.1 to 0.9 per cent. or that of ammonium citrate by equivalent amounts produced more rapid synthesis. A comparison of ammonium acetate, bicarbonate and citrate with urea showed that comparable synthesis occurred at similar concentrations of N, except that synthesis with citrate was very variable. The optimum proportion of inoculum to inorganic medium was 60 in 333 ml.; larger inocula depressed protein synthesis. The protein content of the inoculum was closely related to the greatest protein concen-

SIROTNAK, F. M., DOETSCH, R. N., BROWN, R. E. and SHAW, J. C. **Amino acid metabolism of bovine rumen bacteria.** *J. Dairy Sci.*, 1953, **36**, 1117-1123. [Dept. Bacteriol., Univ. Maryland, College Park.]

Mixed suspensions of bovine rumen bacteria were tested for their ability to degrade individual amino-acids, and the effects of carbohydrates and the substrate level of the amino-acids were investigated.

Six of the 22 amino-acids tested were dissimilated by the rumen organisms with the production of CO_2 , NH_3 , acetic, propionic and butyric acids and, from cystine or cysteine, hydrogen sulphide. Neither ketone bodies nor lactic acid was produced. Glutamic acid, serine, arginine, cystine and cysteine were dissimilated mainly to acetic acid, and aspartic acid to propionic acid. Aspartic acid and urea were attacked five times as rapidly as glutamic acid, serine, arginine, cystine or cysteine; 5 μM aspartic acid or urea was the greatest amount which could be completely dissimilated in 2 hr. under the experimental conditions. The greatest production of NH_3 and CO_2 from aspartic acid was recorded at pH 6.9.

Maltose, and to a similar extent glucose and cellobiose, significantly increased dissimilation of aspartic acid. This stimulation ceased when the maltose had been exhausted. Similar results with the other 5 amino-acids were obtained only in large scale dissimilation experiments, because of the much lower normal rate of dissimilation of these acids.

The relationship between these experiments and the chemical reactions in the rumen is discussed.

PRESCOTT, J. M. **Rumen microorganisms, effects of diet and antibiotics on utilization of non-protein nitrogen.** *J. Agric. Food Chem.*, 1953, **1**, 894-896. [Dept. Biochem. Nutrit., Texas Agric. Exp. Stat., College Station.]

Centrifuged rumen liquor freed from protozoa and most of the plant particles was incubated with 0.15 per cent. urea and 1.0 per cent. glucose. The changes in urea plus ammonia N were followed with and without the addition of antibiotics. Aureomycin, terramycin, bacitracin and L-phenylamine penicillin in concentrations ranging from 1 to 300 μg . per ml. depressed the utilisation of N.P.N., and the depression increased with concentration.—A. T. Phillipson.

EISENSTARK, A. and SANFORD, P. **The action of antibiotics on intestinal flora of poultry. 1.**

Vol. 24, No. 2

Bacterial counts in chickens fed varying levels of Aurofac.

EISENSTARK, A. and DRAGSDORF, R. D. **2. Effect on the growth of intestinal bacteria *in vitro*.** *Poultry Sci.*, 1953, **32**, 837-839; 840-845. [Dept. Bacteriol., Kansas State Coll., Manhattan.]

1. Six pairs of chicks received diets unsupplemented or with Aurofac at 1, 2, 4, 5 or 10 lb. per ton of feed. The chicks were killed when 8 weeks old. Intestinal contents were inoculated quantitatively into media designed to give total counts of aerobic and anaerobic saprophytic bacteria, aerobic counts, and counts of lactobacilli, enterococci, coliform bacteria and yeasts. Significant changes which could be related to the different levels of Aurofac were not found.

2. The effect was investigated of low concentrations of antibiotics on the growth of bacteria isolated from the intestines of 8-week-old chicks and on stock cultures including *Pasteurella* and *Salmonella*. The effect on the morphology of individual bacterial cells was studied with the electron microscope.

Growth of bacteria in plates round pads containing antibiotics was stimulated or inhibited and in some cases both stimulated and inhibited. The numbers of the cultures stimulated and the degree of stimulation were greater round pads soaked in caecal filtrates from birds receiving an Aurofac-supplemented diet than round the caecal filtrate of birds receiving no Aurofac. No inhibition of growth was seen round caecal filtrates from birds receiving Aurofac, and only two of the Aurofac-containing commercial feeds investigated caused inhibition of growth of the bacteria. Generally filtrates from Aurofac-containing feeds stimulated growth. Filtrates from the caeca of chicks receiving an Aurofac-supplemented ration caused as much stimulation of bacterial growth as filtrates from the Aurofac-supplemented feedingstuffs. Nutritional components of filtrates of the caecal contents and the feedingstuffs cannot be excluded as contributing to the stimulation.

Electron micrographs showed that in the stimulated areas enlarged cells and cells of filamentous form were frequently found. Assuming equal viability for "normal" and "stimulated" cells, the cell volume of the "stimulated" cells was 10 to 100 times that of "normal" cells. It is suggested that stimulation of some bacterial cells may take place in the intestine of birds receiving antibiotics.—M. J. Masson.

HOFMANN, K. and SAX, S. M. **The chemical nature of the fatty acids of *Lactobacillus casei*.** *J. Biol. Chem.*, 1953, **205**, 55-63. [Dept. Biochem., Sch. Med., Univ. Pittsburgh, Pa.]

Large batches of *Lactobacillus casei* 7469 were grown on a semi-synthetic medium in carboys. The bacteria were collected by centrifuging and extracted with acetone and ether to yield "free" lipids and subsequently, after hydrolysis with 2N H₂SO₄, to give "bound" lipids. The lipids were saponified and the fatty acids were methylated to yield esters, which were fractionated in a spinning-band semi-micro Piros-Glover column.

Of the 2.9 per cent. of total lipids in the organisms, 21 per cent. was directly extracted with acetone and ether and 79 per cent. was extracted after acid hydrolysis. The major component fatty acids of the bound lipids were palmitic acid 23 per cent., *cis*vaccenic acid 38 per cent., lactobacillic acid 16 per cent. and stearic acid 4 per cent.; the fatty acid composition of the free lipids was much the same.—G. A. Garton.

MCLAREN, A. D. and KNIGHT, C. A. **The response of *Leuconostoc mesenteroides* P-60 to some compounds related to lysine.** *J. Biol. Chem.*, 1953, **204**, 417–422. [Dept. Soils, Univ. California, Berkeley.]

Leuconostoc mesenteroides was unable to use in growth a number of compounds related to lysine, and is therefore an excellent organism for estimat-

ing lysine. Five compounds, including 3 polylysins, inhibited the utilisation of lysine.

D. Duncan.

2222

NIELSEN, N. and NILSSON, N. G. **Investigations on the phosphorus metabolism of *Rhodotorula gracilis*.** 1. **The influence of the phosphate content of the nutrient solution on the formation of fat.**

NILSSON, N. G. and NIELSEN, N. 2. **Phosphate and phosphatide amounts in protein yeast and fat yeast.** *Acta chem. scand.*, 1953, **7**, 984–986; 1067–1070. [Royal Inst. Technol., Stockholm.]

1. Reduction of the phosphate content of the nutrient solution below 0.5 g. KH₂PO₄ per litre caused a reduction in the protein content of the yeast, associated with a rise in fat content. When both N and P concentrations were reduced the fat again rose, but not to the same level as when N alone was reduced. This is evidence that P is necessary for fat formation and confirms the findings of Smedley MacLean and Hoffert (*Biochem. J.*, 1923, **17**, 720; 1924, **18**, 1273).

2. Analyses of 3 samples each of protein yeast and fat yeast are reported (see also Abst. 4616, Vol. 19); the sum of protein and fat in each was relatively constant at about 65 per cent. The higher the amount of fat in the yeast, the lower the amount of phosphatide in the fat, the values being from 3 to 5 per cent. in the high- and from 30 to 40 per cent. in the low-fat yeast. The phosphatide content of the fat-free yeast varied little, from 3.2 to 5.5 per cent., thus supporting the view of Belin (*Bull. Soc. Chim. biol.*, 1926, **8**, 1081–1120) that a certain amount of phosphatide is necessary for micro-organisms.—D. Harvey.

MISCELLANEOUS FEEDING EXPERIMENTS

2223

TOMARELLI, R. M., LINDEN, E., DURBIN, G. T. and BERNHART, F. W. **The effect of mucin on the growth of rats fed simulated human milk.** *J. Nutrition*, 1953, **51**, 251–259. [Nutrit. Div., Wyeth Labs., Inc., Mason, Mich.]

Young rats received a commercial infant food resembling early human milk and given either liquid or dry. The diet supported limited growth; all the animals in one group died, but in a second group there was no death in 11 weeks. Mucin from pig stomachs, added as 5 per cent. of the solids, supported good growth, but was much less valuable when hydrolysed. A synthetic mixture providing an amount of N similar to that in the mucin was about as valuable as hydrolysed mucin. The beneficial effect of mucin was obtained also with a purified diet. It protected rats against

the toxic effects of iodinated casein when this was added to the infant diet.—D. Duncan.

2224

PICCONI, M. **Alcuni antibiotici come fattori di crescita per il ratto. [Some antibiotics as growth factors for the rat.]** *Boll. Soc. ital. Biol. sper.*, 1953, **29**, 322–324. [Ist. Chim. Biol., Univ. Bologna.]

Groups of young rats fed on a complete diet were given daily from 30 to 150 days of age aureomycin 2.5, terramycin 2.5, or streptomycin 5 mg. Those receiving antibiotics established within the first 15 days a small superiority in growth over those not so treated. The superiority did not subsequently increase; it was on the average about 15 g. for males and 10 g. for females.

The reproducibility of the caries scoring methods for rats and the influence of gluten on experimental rat caries.** *Internat. Ztschr. Vitaminforsch.*, 1953, **25**, 42-54. [Netherlands Inst. Nutrit., Amsterdam.] German and French summaries.
- The system of scoring described by Keyes (Abst. 1070, Vol. 15) for use with hamsters was modified for use with rats. Fifteen animals were examined on 3 occasions by the same investigator and it was concluded that only when the score for a particular lesion was 0.5 or more was the agreement between examinations good. Differences in incidence of between 1 and 4 per cent. could be detected.
- With the same system the incidence of caries was examined in rats given the diet of Hoppert *et al.* (Abst. 569, Vol. 2), the same diet with 40 and 20 per cent., respectively, of yellow maize and wheat gluten instead of 60 per cent. yellow maize, or a stock diet on which caries was known to occur. In P generations replacement of maize by gluten caused a reduction in the incidence of caries but in F₁ generations the advantage disappeared. The data for stock diet animals did not support the view of other workers that caries produced by the Hoppert diet is primarily a fissure caries.
- Parts 1 and 2 of this series appeared in Dutch by Jansen *et al.* and by Nederveen-Fenenga and Dalderup in *Tijdschr. Tandheelk.*, 1951, **58**, 2; 321.

HELMAN, E. Z. and MITCHELL, D. F. **Lactobacilli and dental caries in the hamster.** *J. Dent. Res.*, 1953, **32**, 596-600. [Sch. Dent., Univ. Minnesota, Minneapolis.]
- Female hamsters in 3 groups received a basal diet of wheat flour, powdered milk, maize starch, alfalfa meal and sodium chloride, in one group with added sugar and in another with water containing 20 p.p.m. NaF. No correlation was found between caries incidence and counts of *Lactobacillus acidophilus* in their saliva. The relation found to exist between counts of lactobacilli and coliform bacteria suggested that intestinal lactobacilli introduced into the mouth during coprophagy may affect the true lactobacillus count of the saliva.
- In a second group of hamsters, offspring of these females, weaned on the basal diet and later given the high-sugar diet, correlation between occlusal scores and lactobacillus counts was significant at one examination, but not at a later re-examination. The possibility of faecal contamination makes the significance of these findings doubtful. [The figures for percentage composition of the basal diet give a total of only 85.]

ZARROW, M. X., LAZO-WASEM, E. A. and SHOGER, R. L. **Estrogenic activity in a commercial animal ration.** *Science*, 1953, **118**, 650-651. [Dept. Biol. Sci., Purdue Univ., Lafayette, Ind.]
- When castrated mice were fed on a commercial ration there was evidence from the uterine weights that the diet contained an oestrogen. The suspected food was extracted with light petroleum and the extract, after removal of the solvent, was taken up in oil and assayed against oestradiol.

The results revealed that 1 kg. of the diet had an oestrogenic potency equivalent to 3.75 μ g. oestradiol. The oestrogen and its source were not identified. The use of such a diet might easily invalidate many experiments and would interfere with an assay for oestrogen.—W. Godden.

FEURT, S. D. and FOX, L. E. **Effects of oral administration of Spanish moss, *Tillandsia usneoides* L.** *Science*, 1953, **118**, 626–627. [Dept. Pharmacognosy, Coll. Pharm., Univ. Florida, Gainesville.]

Two groups of adult rats, 5 males and 5 females in each, were fed on commercial dog cubes with or without an equal weight of ground Spanish moss. After 30 days they were allowed to mate and after a further 23 days a litter of 12 was born to a female in the group receiving no moss and a litter of 5 to a female in the other group. The first litter grew normally, but the second failed to grow and all died before they were 20 days old. The other females on the dog cubes reproduced normally but those receiving moss failed to reproduce. It is suggested that the waste material from processing of fibres from the moss for the upholstery

industry might be used as a source of oestrogens for beef cattle, to improve meat quality and the efficiency of feed utilisation.—W. Godden.

SILBERBERG, M. and SILBERBERG, R. **Keratomalacia and panophthalmitis in "yellow" mice.** *Amer. J. Pathol.*, 1953, **29**, 951–961. [Snodgrass Lab., Hosp. Div., St. Louis, Mo.]

The mice were of strain YBR/Wi, in which yellow animals show hereditary obesity and diabetes while their grey littermates do not. Both colours and both sexes were included in the 252 mice, groups of which received a stock chow diet, a 30 per cent. fat or a 79 per cent. carbohydrate diet.

Mice of both colours developed changes in the eyes, beginning with corneal capacity. The eyeballs became prominent, corneal ulcers developed and the inflammatory process spread to the whole eye and the eyelids. The incidence was somewhat less in females than in males, and the onset was later on stock diet than on high fat or high carbohydrate intake.

The possible role of vitamin A in the etiology of the lesions is discussed.—D. Duncan.

SUNDARAM, T. K. and SARMA, P. S. **Tryptophane metabolism in rice moth larva (*Corcra cephalonica* St.).** *Nature*, 1953, **172**, 627–628. [Biochem. Lab., Univ. Madras.]

Rice moth larvae, when fed on a diet containing 1 per cent. DL-tryptophan or DL-kynurenine, gave yellow faeces; with 0.5 per cent. D-tryptophan the faeces were white. Unlike mammals, these larvae did not convert the kynurenine to xanthurenic acid.

D-Amino-acid oxidase activity in extracts of larval tissue was low, as the extracts failed to liberate ammonia from D-tryptophan.

Paper chromatography suggested that the larval excretory pigments were hydroxykynurenine and kynurenine or a derivative thereof. DL-Tryptophan and DL-kynurenine in the diet yielded almost identical patterns.—D. Duncan.

VENKATACHALA MURTHY, M. R. and SREENIVASAYA, M. **Effect of antibiotics on the growth of the silkworm, *Bombyx mori* L.** *Nature*, 1953, **172**, 684–685. [Indian Inst. Sci., Bangalore 3.]

When silkworm larvae were given aureomycin or chloromycetin as supplement to mulberry leaf there was an increase of from 9 to 10 per cent. in larval and pupal weight and a decrease of from 5 to 8 per cent. in output of silk. When the supplement was an amino-acid mixture approximating in composition to casein, larval weight increased by 15 per cent., pupal weight by 8.5 per cent. and silk output by 2.5 per cent. When both antibiotic and amino-acid mixture were given, weight increased again and silk output increased from 8 to 14 per cent. Similar trends but less pronounced increases were observed when an amino-acid mixture was given approximating in composition to silk fibroin. Terramycin alone or in combination with the amino-acid mixtures had no effect on growth or silk production.—F. C. Aitken.

SCHNEIDERMAN, H. A. and WILLIAMS, C. M. **The physiology of insect diapause. 7. The respiratory metabolism of the Cecropia silkworm during diapause and development.** *Biol. Bull.*, 1953, **105**, 320-334. [Biol. Labs., Harvard Univ., Cambridge, Mass.]

Respiratory measurements in a Warburg apparatus were made on 150 larvae, pupae and developing adults of the giant silkworm *Platysamia cecropia* and a few pupae of *Samia walkeri*. All were kept at 25° C.

There was a striking and precipitous decrease in rate of O₂ consumption from the time of spinning the cocoon to pupation, from a larval rate of over 1100 c.mm. per g. tissue per hr. to a pupal rate of 16.3 ± 9 . The low rate persisted throughout the diapause. Increasing metabolism appeared a week before visible initiation of adult development, and increased until just before the emergence of the adult moth, when the rate was 312 c.mm. per g. initial pupal weight per hr.

Though O₂ utilisation was almost constant, CO₂ output by diapausing pupae occurred in "bursts" every few hours. The estimation of R.Q. therefore called for long experiments, of at least 17 hr., to encompass two or more CO₂ releases. The average R.Q. was 0.78, S.D. ± 0.093 . After minor injury to the integument the rate of O₂ consumption increased on the average to 287 ± 59 per cent. of the resting value, the increase persisting for some days. The R.Q. was unchanged and the response was not affected by implantation of phenylthiourea. Despite the increase in metabolism after injury, sometimes up to 14-fold, no development was initiated.—D. Duncan.

LUDWIG, D. and WUGMEISTER, M. **Effects of starvation on the blood of Japanese beetle (*Popillia japonica* Newman) larvae.** *Physiol. Zool.*, 1953, **26**, 254-259. [Dept. Biol., University Coll., Univ. New York.]

Larvae of the Japanese beetle collected in autumn and winter were stored until required and were then allowed to feed for 2 weeks, after which they were kept in glass tubes and starved for 1, 2, 3 or 4 weeks in a moist atmosphere. In these

conditions the water content and osmotic pressure of the blood remained constant during the period of starvation. There was no significant change in the protein N of the blood, but amino-N and N.P.N. increased. The fat content increased during the first 2 weeks and then decreased. The reducing substances increased throughout the 4 weeks. It is considered that the blood does not serve as a reservoir for sources of energy during starvation, but that the changes in blood constituents may reflect metabolic changes elsewhere.

DIET AND HEALTH

REQUIREMENTS

2246

MOLCHANOVA, O. P. **Sravnitel'nye dannye o normakh pitaniya naseleniya v SSSR i S.Sh.A. [Comparative data on the standards of nutrition of the population in the U.S.S.R.**

Vol. 24, No. 2

and U.S.A.] *Gigiya Sanit.*, 1953, No. 3, 40-42.

Nutrition standards proposed by the U.S. National Research Council in 1948 are compared with those proposed by Soviet scientists. There are considerable differences, particularly in protein

allowances. The Soviet proposals are 140 to 160 g. protein daily for a man on heavy work, the energy from protein forming about 14 per cent. of the total energy intake. The corresponding figure suggested by the National Research Council is 70 g., equivalent to about 6 per cent. of the total energy in the form of protein. The National Research Council standards differ considerably for men and women on heavy work, 4500 and 3000 Cal. daily; the Soviet figure is 4500 to 5000 Cal. for men or women on heavy work.—W. Hughes.

FEEDING OF INFANTS AND CHILDREN

2247

Discussion on some problems of prematurity.

STEVENSON, S. S., WIRTH, P., BASTIANI, R. and DANOWSKI, T. S. **Some effects of exogenous thyroid or thyroxin upon premature infants.** *Pediatrics*, 1953, **12**, 263-271. [Elizabeth Steel Magee Hosp., Pittsburgh, Pa.] Spanish summary.

Forty-eight premature infants of birthweight about 1500 g. were studied. Twenty-four were given capsules containing dried thyroid or pills containing thyroxine. Twenty-four controls were given capsules or pills containing lactose. Treatment began when infants were taking enough food to gain in weight, at 10 days of age in controls and 8 days in the study group. The average weights were then 1670 g. and 1590 g., respectively. Treatment was given on the average for 25 days in the control group and 26 days in the study group.

Daily doses of 60 or 120 mg. dried thyroid had no significant effect on clinical condition and progress or on protein-bound I level in serum. Daily intake of 180 mg. dried thyroid or of 0.2 mg. thyroxine did not affect energy and fluid intakes, incidence of gavage, amount of vomiting, skin colour or body temperature but decreased weight gain and increased pulse rate, incidence of diarrhoea and level of protein-bound I as compared with controls.—F. C. Aitken.

BLAICKLEY, J., CLARKE, S., MACKEITH, R. and OGDEN, K. M. **Breast-feeding: factors affecting success: a report of a trial of the Woolwich methods in a group of primiparae.** *J. Obstet. Gynaecol. Brit. Empire*, 1953, **60**, 657-669. [Dept. Obstet., Guy's Hosp., London.]

In the British Hospital for Mothers and Babies, Woolwich, measures are applied during pregnancy and the puerperium to prevent overdistension of the breasts in the first week of the puerperium. These measures, which in a controlled experiment doubled the proportion of primiparae successfully breast feeding their babies for 6 months, are briefly as follows: the use of glass nipple shields from the 20th week of pregnancy or earlier to correct poor protractility; massage of the breasts and expression of colostrum for the last 4 to 8 weeks of pregnancy; regular removal of surplus milk; and judicious use of stilboestrol during the puerperium. In this trial these measures were applied to 117 primiparae with 117 controls delivered in hospital, and the antenatal measures were applied to 66 primiparae with 64 controls delivered at home.

Of the women delivered in hospital 51 per cent. of those given Woolwich treatment and 26 per cent. of the controls successfully breast fed their infants for 6 months. The difference was statistically significant. There was no significant difference between the performances of control and treated women delivered at home. It was concluded that the important part of the Woolwich method was the treatment during the puerperium. It is recommended that massage and expression should be learnt antenatally so that they can be used in the lying-in period. The early use of glass nipple shields had a beneficial effect on nipples which were poorly protractile and is recommended in such cases.—F. C. Aitken.

GOUNELLE, H. and DEMARCHI, M. **Nutritional status of infants and very young children in Baghdad.** *J. Fac. Med. Baghdad, Iraq*, 1953, 17, 42-53. [Baghdad.]

Weight curves from birth to 18 months of age were drawn from data for 1842 infants attending 2 welfare centres; all came from the labouring class. The curve of mean weights was the same as for European children up to the age of 2 months but then fell below European standards, the difference becoming still greater after 7 months. Breast feeding alone was used for 58.7 per cent. of infants, breast feeding with supplements for 32.1 per cent. and cow's milk for 9.2 per cent.; the mean weight of the breast-fed infants was greater than that of the infants in the other groups at all ages up to 12 months but thereafter was definitely lower. The amount of cows' milk given

Vol. 24, No. 2

was nearly always inadequate. Recommendations for the improvement of infant nutrition are put forward.—L. Wills.

DIETARY SURVEYS AND INDIVIDUAL STUDIES

2259

DE WAART, A. *et al.* Voeding en voedingstoestand van schoolkinderen en een groep jonge arbeider te Leiden (1950-1951). [Diet and nutritional status of schoolchildren and a group of young workers at Leyden (1950-1951).] *Nederl. Inst. Praev. Geneesk., Rep. No. 22*. H.E. Stenfort Kroese N.V., Leyden, 1953, pp. xv + 190. English summary.

An introductory chapter describes the origin of this study and the general procedures adopted. The schoolchildren were a random sample, from an alphabetical list, of the children aged 6, 7, 8 and 9 in 3 groups of schools roughly representative of 3 social classes. The first study, of 111 children, was in October to December and designed to give the "after summer" state; the second from April to July, with 198 children, to show the "after winter" condition.

Chapter 1 describes the sociological background and clinical examination, including somatometric data, clinical evaluation, and signs of deficiency, with a summary and commentary.

Chapter 2 reports on the diet of the children estimated by one-day history and checked against family food consumption for the week in which the clinical examination was made. The same procedure was used with 61 apprentices at a technical school.

Chapter 3 describes the biochemical analyses made and chapter 4 summarises and discusses the data in English.

In all 210 children were examined, 99 of them twice. The aim was to look for interrelations between diagnostic signs used in routine examination (height, weight, general appearance, "sub-clinical deficiency-symptoms", Hb and others), and biochemical data and estimates of diet. The

"sub-clinical" signs described are angular stomatitis, magenta colour of tongue, xerosis of skin, atrophy and hypertrophy of the tongue papillae, folliculosis of the skin and staring hair. Of these the first 4 showed a significant social gradient and the last appeared only in the poor group. The first 2 were significantly more frequent in spring. But there was no significant difference in vitamin A, carotenoids or vitamin C in the serum of children with and without xerosis, or in riboflavin intake in those with and without angular stomatitis, or in nicotinic acid intake between those with and without atrophic papillae.

There were significant differences in height, weight and sitting height between the well-off and the poor but not between the upper and middle classes. With the difference between total and sitting height as a measure of leg length and of development, a year's delay is estimated for the poor. There were significant correlations of height and weight with energy intake, total and animal and vegetable protein and vitamin C, but not vitamin A or riboflavin. Social class differences were significant except for energy. Hb was significantly correlated with both height and weight but serum protein was not related to either. The *peledisi* index was not correlated with height or weight but agreed well with general clinical assessment of state of nutrition: $r = +0.451$. It was not related to any of the biochemical or diet assessments except total serum protein. Skeletal age showed significantly more retardation among poor children, and skeletal retardation went with significant deficits of height and weight and differences of serum Ca, P and phosphatase, of which none was significant. Finally, there were significant differences between well-to-do and poor in respect only of vitamin A and carotenoids in serum and between well-to-do and middle class for only vitamin C in serum.

Biochemical data for the apprentices and vitamin C in serum for 39 medical students are detailed for comparison.—I. Leitch.

GLAJA, A. Prilog poznavanju ishrane seoske dece školskog doba. [Contribution to the study of the nutrition of village schoolchildren.] *Rev.*

Trav. Acad. Serbe Sci., 1953, 28, *Inst. Nutrit.*

No. 2, pp. 37. In Serbian: French summary.

Studies made in 1948 in 2 Serbian villages, presented in tables with French headings, showed that village schoolchildren were inferior to town children in both height and weight. Measurements at 6-monthly intervals revealed that they lost weight during the winter and gained about twice as much in height during the summer as during the winter. These findings are ascribed to inadequate feeding. Children may have to walk long distances to school. They bring their own lunch. Investigation of the lunches in a village in western Serbia on a day in October, which is the best time of the year for food because wheat bread has not yet been replaced by maize bread, showed that even at that season well over a third had maize bread as the principal item. Other frequent lunch items were cheese and kajmak (salted cream). On the average the boys' lunches provided 925 Cal., 32 g. protein and 22 g. fat and the girls' lunches 833 Cal., 27 g. protein and 21 g. fat. Bread supplied about half the protein and 70 per cent. of the energy. Wednesday and Friday, however, are fast days and on these more than half the children brought nothing but dry bread; the corresponding energy and nutritive values were 652, 16, 4; 622, 15, 5.5. Numerous fast days and longer periods of fasting are observed by Serbian peasants of the Orthodox Church; in some families there are as many as 240 days in the year on which no food of animal origin is taken.

The improvement of the feeding of country children is a matter of education in nutrition rather than of economics; better instruction of parents and children and the introduction of school canteens are recommended. (From summary.)

WYATT, S. and MARRIOTT, R. Night work and swift changes. *Brit. J. Indust. Med.*, 1953, 10, 164-172. [Med. Res. Counc. Group Res. Indust. Psychol.]

An investigation was made in 1945-46 in 3 works, one of which had a weekly, one a fortnightly and one a monthly change of shift from night to day. One was a rolling mill, another made wagon wheels and the third made motor vehicles. The investigation was mainly non-nutritional but, as a small part of it, 150 of the men were asked about their meal habits. Seventy per cent. brought food,

N.A. and R., April 1954

whether on night or day duty. Various reasons were given for not wanting to use the canteen. Almost all the men ate sandwiches during short breaks whether the canteen main meal was taken or not. The percentage enjoying their food better when on the day shift was 74, on the night shift 3.3 and noticing no difference 22.7. The reasons given for lack of enjoyment on the night shift were the unnatural hours and stomach trouble. The percentage settling down at once to the changed meal-times was 61.3 on transfer from night to day, and 37.3 on changing from day to night. The remainder took varying times to adapt themselves, and a certain number, about a quarter, never became adjusted to the night shift. About 20 per cent. said changing over caused indigestion, more noticeable on starting night shift. None of them had given up night work because of stomach trouble, but none was interviewed among those who worked only the day shift and who might, therefore, have given up night work in the past because of stomach trouble.

E. M. Hume.

2264

FULD, H. and ROBINSON, K. V. **Malnutrition in the elderly.** *Lancet*, 1953, **265**, 860-864. [Newsham Gen. Hosp., Liverpool.]

An account is given of the signs and symptoms in 39 cases of malnutrition admitted to hospital. Thirty-three of the patients were over 60 years of age.

There were some signs of deficiencies of B vitamins; scurvy was diagnosed in 19 on 4 bases, gross shortage of fruit and fresh vegetables in the diet, haemorrhages in skin, subcutaneous tissue and joints, positive Hess test and significant results with saturation tests. All but 3 of the 39 were anaemic; the incidence of achlorhydria was somewhat higher than normal for elderly people.

Response to diet treatment was good, but a follow-up of 12 patients showed that after discharge from hospital 6 had relapsed to poor diets. The economic and social backgrounds of the patients are briefly described.—F. C. Aitken.

2265

TUCKER, R. E., CHALMERS, F. W., CHURCH, H. N., CLAYTON, M. M., FOSTER, W. D., GATES, L. O., HAGAN, G. C., STEELE, B. F., WERTZ, A. W. and YOUNG, C. M. **Cooperative nutritional status studies in the Northeast Region. 4. Dietary findings.** *Rhode Island Agric. Exp. Stat. Bull.* No. 319, June 1952, pp. 24.

4. For earlier papers in this series see Absts. 140, Vol. 22; 3430, 3391, Vol. 23.

Food consumption by 1804 persons, 854 males and 950 females, was measured in 6 States, generally by 7-day diet records. The subjects were classified in the 6 age groups for which the U.S.

National Research Council has made recommendations for allowances of nutrients, and mean intakes of these with standard deviations are tabulated for each age group at the individual centres.

From comparisons of these with the National Research Council recommendations the general conclusion was that shortages of ascorbic acid, calcium, vitamin A and riboflavin were common and that of these the deficiency of ascorbic acid was the most widespread and the greatest. The requirements of the younger age groups were more nearly met than were those of the older groups, and the needs of males than those of females. It is suggested that increased consumption of dairy products, fruit and vegetables would be advantageous in the north-east of the United States. (See also next Abst.)—D. Harvey.

2266

CLAYTON, M. M., BABCOCK, M. J., FOSTER, W. D., STREGEVSKY, S., TUCKER, R. E., WERTZ, A. W. and WILLIAMS, H. H. **Cooperative nutritional status studies in the Northeast Region. 5. Blood findings.** *Maine Agric. Exp. Stat. Bull.* No. 516, May 1953, pp. 59.

5. Data on Hb, ascorbic acid, vitamin A, carotene and alkaline phosphatase in blood were collected. The number of subjects varied with the estimations but values were obtained for Hb for more than 3000 subjects. They were from the 6 States, but in Massachusetts only pregnant women were studied.

For Hb no age or sex difference was found between ages 4 and 10. Between 10 and 12 there was a rise in both sexes which continued beyond 13 years in the boys but not in the girls. Ascorbic acid fell with increasing age and there was no marked sex difference until the age 13 to 15 years was reached, when values for boys were significantly lower than for girls; this sex difference continued in the higher age groups. Values for vitamin A for the whole survey showed no age or sex difference but some did exist for the same age and sex groups in different States. The greatest number of low values appeared in the 13 to 15 age group for both sexes; nearly 10 per cent. of the subjects of that age had values below 20 μg . per 100 ml. blood. Differences in carotene content were less consistent but it was again the 13 to 15 age group that showed most low values, with the males tending to be affected to a greater extent than the females. Data for alkaline phosphatase were collected at only 2 centres. In both sexes the mean value reached a maximum between 5 and 6 millimole units before puberty, and few values above 10 units were recorded. [A "millimole unit" is the activity liberating 1 mM nitrophenol per litre serum per hour from disodium *p*-nitrophenyl phosphate substrate.] After puberty

there was a marked decline in the value for girls, and the smaller decrease which occurred at this time in the boys gave rise to a distinct sex difference at 13 years and above.

The data are fully tabulated in 20 pages of the bulletin. For earlier papers in this series see Absts. 140, Vol. 22; 3430, 3391, Vol. 23, and preceding Abst.—D. Harvey.

2267

MOSER, A. M. **Menu patterns and food preferences in South Carolina.** *S. Carolina Agric. Exp. Stat. Bull.* No. 406, June 1953, pp. 49.

This report on the food habits of South Carolina people is based on an analysis of menus. About 400 city and farm men in 2 counties were interviewed and 149 farm families in the tobacco area were asked to keep records for 1 week of foods used and meals served.

The importance of regulating programmes for improved nutrition to local food patterns and preferences is stressed.—F. C. Aitken.

2268

DICKINS, D. and SHEETS, O. A. **Enrichment of whole ground corn meal in diets of farm-operator families.** *J. Amer. Dietetic Assoc.*, 1953, **29**, 873-877. [Dept. Home Econ., Mississippi Agric. Exp. Stat., State College.]

In a diet study of 429 farming families (Reagan and Crossman, *U.S. Dept. Agric. Information Bull.* No. 41, October 1951) 84 per cent. (361) consumed whole ground maize meal, 2.4 lb. per head, during the week of study. The intakes of vitamin B₁, riboflavin, nicotinic acid and Fe of most of these 361 families reached the levels recommended by the National Research Council. The proportions not reaching these levels were highest in the lower socio-economic groups. Enrichment of whole ground maize meal would have resulted in more families in these groups reaching the recommended allowances of the nutrients, especially of nicotinic acid.—F. C. Aitken.

2269

COLLAZOS C., C., WHITE, H. S., REH, E., HUENEMANN, R. L. and WHITE, P. L. **Dietary surveys in Peru. 1. San Nicolás, a cotton hacienda on the Pacific coast.** *J. Amer. Dietetic Assoc.*, 1953, **29**, 883-889. [Dept. Nutrit., Minist. Pub. Health, Lima, Peru.]

A representative sample of the population, 35 families, was studied for one week. Foods were weighed when possible. Nutrient intakes were computed from tables of composition of Peruvian foods (in the press) and were compared with recommended intakes derived from U.S. National Research Council, Instituto de Nutrición de Centro América y Panamá and FAO recommenda-

tions. Fifteen to 30 per cent. of the families had less than 75 per cent. of the recommended intakes of calories, protein, nicotinic acid and ascorbic acid. Half of the families had 75 per cent. or less of the allowances of vitamins A and B₁. Three-quarters of the families had less than 75 per cent. of the allowances of Ca and riboflavin.

Simple improvements in the diets could be effected by increased consumption of turnip greens, sweet potatoes and dried peas and beans. It is not possible to increase consumption of milk and milk products.—F. C. Aitken.

2270

LAL, S. B. **Consumption level of depressed classes (Nonia and Chamar) in Champaran (Bihar).** *J. Indian Med. Assoc.*, 1953, **22**, 492-495. [Pub. Health Lab., Patna.]

The diet of 50 Nonia families and 64 Chamar families, consisting of 242 and 347 persons, respectively, was surveyed. The method of study was described previously (Abst. 2571, Vol. 21). Consumption of foods and intake of nutrients per consumption unit are tabulated. The diets were considered to be adequate in energy but low in animal protein, Ca and vitamin A. Consumption of milk and milk products and of leafy vegetables was low.

Heights and weights of children were recorded; nutritional state was assessed and the percentages of boys and girls in different grades are shown. The incidence of xerophthalmia, phrynoderma, angular stomatitis and Bitot's spots in girls and boys is tabulated. There was little difference in nutritional condition between Nonia and Chamar children.—F. C. Aitken.

La alimentación en los hospitales dependientes del Ministerio de Salud Pública de la Nación. 1. El regimen de la alimentacion normal. [**Diet in hospitals attached to the Ministry of Public Health. 1. Normal diet.**] *Inst. Nac. Nutricion, Argentina, Publicaciones Cientificas CNP.* 33, 1953, pp. 70.

To simplify the work in hospital kitchens, a normal basic dietary regimen has been established, in conformity with Escudero's recommendations, to meet the requirements of patients who are not in need of special diet treatment. The total energy value of this normal basic ration is 2600 Cal., and supplements are added for those with greater requirements. Tables give the quantities of each type of food required to make up the daily ration, the equivalents of other replacement foods and details of the variants used to raise the energy value to 2800 or 3000 Cal. Factors of correction are given for all the foods listed to show the quantities "as purchased". To provide variety in the menus, 8 different lists of foods complying with the requirements of the basic ration and brief indications of the method of cooking are given, and there is a plan to show the use of one of these listed diets.—M. B. Richards.

BUCHER, K., MUMENTHALER, A. and WEISSER, K. Zur Frage der Verträglichkeit von Süßmost. [**Tolerance of unfermented grape juice.**] *Schweiz. med. Wochenschr.*, 1953, **83**, 735-739. [Pharmacol. Anst., Univ. Basle.]

Vol. 24, No. 2

Studies were made on about 400 subjects of the effect of consuming large amounts of unfermented grape juice with reference to sensations in the mouth, stomach and intestine. On the whole the juice was well tolerated. About 6 per cent. experienced gastric discomfort, and from 6 to 15 per cent. complained of a sensation of fullness. In spite of the high energy value of the juice no effect on appetite was observed.—A. M. Copping.

LEASE, E. J. **Corn meal enrichment.** *J. Amer. Dietetic Assoc.*, 1953, **29**, 866-872. [Nutrit. Dept., Clemson Agric. Coll., S. Carolina.]

The maize milling industry in the U.S. consists of a few relatively large mills which produce degermed maize meal and grits and some 8000 small mills which produce mainly whole maize meal. In 1943 South Carolina State Legislature enacted a law requiring the enrichment of all degermed maize meal and grits and requested small mills to enrich their whole maize products. This was followed by a programme of education and technical assistance until in 1949 it was possible to broaden the enrichment law to cover all maize products for use as human food in the State. Similar steps have been taken in some other states. The federal minimum enrichment standard for whole maize meal in mg. per lb. is: vitamin B₁ 2.0, riboflavin 1.2, nicotinic acid 16.0, Fe 13.0, Ca 500.0.—F. C. Aitken.

ORNSTEIN, J. Uitkomsten National Budgetonderzoek 1951. [**Results of the 1951 National Budget Investigation.**] *Voeding*, 1953, **14**, 553–556.
The first report on data from the National Budget Investigation deals with the expenditures of 1003 families of artisans, excluding agricultural labourers, in 1951. This extract deals with mean food expenditure of the whole group and families of 5 or more and of less than 5 persons, classified by residence in Rotterdam and The Hague, other towns of over 40,000 inhabitants and communities of less than 40,000. Food accounts on the average for 37 per cent. of total expenditure, more in large families, less in small, and less in Rotterdam and The Hague than in other urban communities. In comparison with data for 1935–36, there was some increase in consumption of green vegetables, fruit, milk and "genotmiddelen" [luxuries?].—I. Leitch.

COOGAN, J. **Bread and the Soviet fiscal system.** *Rev. Econ. Statistics*, 1953, **35**, 161–167. [Russian Res. Centre, Harvard Univ.]
This detailed discussion, based on Soviet documents, includes a table of items in the cost of production of 95 per cent. extraction rye bread in Moscow for 9 selected years from 1934 to 1950 inclusive. In 1939 tax accounted for 68 per cent. of the retail price of bread, in 1947, 86 per cent. and in 1950, 70 per cent., and reasons are given for the author's belief that bread plays an even larger part in the Soviet fiscal system than is indicated by these figures or is admitted by Soviet authorities. Other data in roubles for 1939 and 1950, respectively, include procurement price of rye grain per 100 kg., 7.66, 9.66; value of 100 kg. rye flour before tax, 20.71, 27.11; retail price

of bread per kg., 1, 2.4. In 1950 milling costs were about $2\frac{1}{2}$ times, transport of flour 3 times and baking costs nearly 4 times as much as in 1939.—W. M. Deans.

2295

SKEOCH, L. A. **Food prices and ration scale in the Ukraine, 1946.** *Rev. Econ. Statistics*, 1953, **35**, 228-235.

The information, collected in the city of Kiev in June and July 1946, when the author was acting chief of the UNRRA Mission to the Ukraine, includes the widely differentiated ration scales for heavy workers, light and medium workers, office workers, dependents and children up to 12 years. Scientists and other privileged workers got much the same rations as heavy workers. The rations for fats and meat could not always be honoured, but children, heavy workers and pregnant and nursing mothers had high priority.

In addition to the ration stores selling at controlled prices there were government-controlled "commercial" stores selling unrationed delicacies

at high prices, and public markets selling surplus products of collective farms at prices several times those of the ration stores. Few people could afford to buy much from these two sources, but many resorted to them from time to time to break the monotony of the rations. During the period studied there was a sharp rise in the price of bread and cereals in the public markets owing to the poor harvest. There was, however, enough bread to meet the rations, though much of it was of rye, possibly with an admixture of coarse grains, and most of the wheat bread was of at least 85 per cent. extraction.—W. M. Deans.

GENERAL STUDIES

2297

KERPEL-FRONTUS, E., VARGA, F. and KOVÁCH, S. **The pathogenesis of infantile athrepsia.** *Ann. paediat.*, 1953, **181**, 129-146. [Dept. Paediat., Univ. Pécs.] German and French summaries.

From observations of the circulation and metabolism of 57 undernourished infants, it appeared that athrepsia (marasmus) occurred when a previously wasted baby became dehydrated. The sequence then was low water content of blood, severe decrease in cardiac output, sub-acute circulatory failure, and a further decline in cellular metabolism. The dehydration was usually due to infective gastro-enteritis in infants who were already underfed, diseased or congenitally deformed.—M. S. Fraser.

2298

FRY, P. C. **A comparative study of "obese" children selected on the basis of fat pads.** *J. Clin. Nutr.*, 1953, **1**, 453-468. [Forsyth Dent. Infirmary Child., Boston, Mass.] Spanish summary.

The 39 obese children were selected from 414 children, aged from 4 to 14 years, taking part in a growth study. Those selected had pads or folds of fat in at least 2 of the 3 regions, dorsal, abdominal and trochanteric. Fifty children were selected at random as a control group.

Vol. 24, No. 2

For the 2 groups data were obtained on blood pressure, height, weight, tooth eruption, wrist ossification, mother's weight gain in pregnancy, weight at birth, ages of teething, walking and talking, rate of advancement towards puberty, protein and energy intakes, family stability, ethnic origin, birth order, illness experience, play activity and personality and habits. The data were analysed statistically.

The results indicated that the obese group tended to be advanced in skeletal development, did not overeat and were not especially prone to illness or accident.—F. C. Aitken.

WALKER, A. R. P. and ARVIDSSON, U. B. **Iron "overload" in the South African Bantu.** *Trans. Roy. Soc. Trop. Med. Hyg.*, 1953, **47**, 536-548. [S. African Inst. Med. Res., Johannesburg.]

In an earlier note the haemosiderosis, then designated haemochromatosis, which is common in Africans was attributed to their high intake of Fe derived largely from iron cooking utensils (see Abst. 4125, Vol. 20). The evidence of a positive connection is examined in more detail and, from further consideration of these large amounts which are consumed, of other diseases likely to produce siderosis and of the incidence of siderosis in other parts of southern Africa, the conclusion that the condition is the direct result of the high intake is thought to be warranted. No evidence was found of haemosiderosis being associated with ill-health in any form.—D. Harvey.

2302

JAFFE, R. Consideraciones sobre la patología geográfica de Venezuela. [*Geography of disease in Venezuela.*] *Acta cientif. venezol.*, 1953, **4**, 86-88.

Arteriosclerosis is infrequent in Venezuela in comparison with European countries and occurs in only minor degrees. This is possibly associated with the low consumption of animal fat. Other relatively uncommon diseases are gallstones, diabetes, gout and rickets, though doctors are not agreed about the first three and there may be differences with social class. On the other hand, angina pectoris is as frequent as in England; but in Venezuela it is due to syphilitic aortitis. Myocarditis is common and may have a number of different causes, since the incidence is different in different parts of the country. Endocarditis and arthritis are infrequent. Essential hypertension seldom occurs among the poor but is as frequent among the well-to-do as in Europe. Thrombosis and embolism are almost unknown. Cirrhosis of the liver is much as elsewhere, but 2/3 of the disease is associated with bilharzia infection. There is nothing outstandingly different in intestinal disease.—I. Leitch.

OOMEN, H. A. P. C. *Infant malnutrition in Indonesia.* *Bull. World. Health Organiz.*, 1953, **9**, 371-384. [Nutrit. Inst., Djakarta, Indonesia.] French summary.

A description is given of the commonly encountered infant malnutrition in Indonesia, based on a recent study of pre-school children in 2 towns. The most frequently observed signs of malnutrition

were emaciation, retarded growth, liver changes, dyspigmentation of hair and skin, other skin lesions, oedema, muscular wasting and hypochromic anaemia. Frequently associated with the general malnutrition syndrome was the more specific sign of vitamin deficiency, xerophthalmia, which responded to treatment with cod liver oil or vitamin A. Eight pictures of cases of kwashiorkor are shown to illustrate the text, but the term kwashiorkor is avoided in the paper because "the name kwashiorkor implies alterations in pigmentation which are not always present in undoubtedly related conditions".

Diet histories of 50 children aged 1 to 3 years showed that in the 2 weeks before examination 47 ate rice daily, 8 had sweet potato or cassava, 16 had eaten some green vegetable daily, 10 had eaten soya or green gram, 7 had been given small quantities of fish, meat or egg, 8 had had some fruit and 7 had been given condensed milk; 14 were still receiving breast milk.

Practical measures for treatment and prevention of malnutrition in Indonesia are indicated.

2305

DE SILVA, C. C., RAFFEL, O. C. and SOYSA, P. *Pattern of children's disease and death as seen in a children's hospital, Colombo, Ceylon.* *Acta paediat.*, 1953, **42**, 453-473. [Dept. Paediat., Univ. Ceylon, Colombo.]

The 3446 illnesses in 2168 admissions to hospital are classified as follows: intestinal parasites 1332, nutritional disorders 683, respiratory diseases 613, gastro-intestinal disorders, excluding intestinal parasites and amoebiasis, 510, nervous disorders 159, miscellaneous 149.

Among the nutritional disorders the most common were fatty liver, oedema and eye conditions such as xerophthalmia, Bitot's spots and keratomalacia. A pre-Bitot pigmentation and what the authors call a "gutter" pigmentation of the lower part of the sclera are described. Kwashiorkor was fairly common. There were 10 cases of rickets and 4 of scurvy which were diagnosed radiologically. Nutritional disorders had a fatality rate of 27.7 per cent.—F. C. Aitken.

LAL, S. B. *Nutritional oedema and consumption level in yet another food scarcity area of Bihar.* *Indian Med. Gaz.*, 1953, **88**, 475-480. [Pub. Health Labs., Patna 4.]

The diet of 100 families was studied in 1951 in the district of Darbhanga. Food consumption

N.A. and R., April 1954

and nutrient intake per consumption unit are tabulated with data obtained in a survey of the same families in 1943. There was serious deterioration in diet quantity and quality, except for Ca intake, which was greater in 1951 than in 1953.

Children and adults were examined clinically. Twenty-one subjects with oedema were found, all adult. The average bodyweights of men and women with and without oedema are presented. There was no statistical difference between those with oedema and those without. On the average both groups were much underweight. Data are presented for range and mean values of Hb, blood sp. gr., plasma sp. gr. and blood protein in 21 adults with and 23 without oedema. The values were not significantly different. Compared with values for normal healthy persons in other parts of the State, only blood protein was significantly lower.—F. C. Aitken.

2308

ALTMANN, A. **Kwashiorkor. Malignant malnutrition—infantile pellagra.** *S. African J. Clin. Sci.*, 1953, **4**, 71–89. [Baragwanath Hosp., Johannesburg.]

The author's published work on kwashiorkor is brought together and the results are reported of a follow-up study of certain of the patients previously examined. True relapse from which the patient might recover could occur; the shortest time before signs reappeared was 50 days. Twenty-two children were readmitted for study from 6 weeks to 2 years after the acute episode. All were in a satisfactory state of nutrition and had gained weight. In 2 patients only was the liver palpable more than 1 finger's breadth below the costal margin. Values for total serum protein were normal, the albumin values had increased slightly but were still below the lower limit of normal, and the γ -globulin values though lower than on discharge were still above the upper limit of normal. Liver biopsy showed small amounts of fat still present in 3 patients only. The response to some liver function tests had become normal but the findings were not consistent. In the acute episodes estimation of duodenal and faecal trypsin had given contradictory results, since the duodenal contents in 41 of 42 patients gave a positive reaction and in 25 of them on whom faecal tests were made the result was negative. Controls gave normal results. At the follow-up examination of 17 patients only three had a normal concentration of faecal trypsin, 2 had little and 12 had none. No explanation could be given.—L. Wills.

2309

VAN OYE, E. La courbe de Price-Jones dans la malnutrition et dans la dénutrition (kwashiorkor) en Afrique. [The Price Jones curve in

Vol. 24, No. 2

malnutrition and in failure of nutrition (kwashiorkor) in Africa.] *Bull. Soc. Pathol. exot.*, 1953, **46**, 611–618. [Inst. Méd. Trop. Princesse Astrid, Léopoldville.]

Previous observation had shown that the Price Jones curve in healthy African infants was normal, and that the mean red cell diameter was 7.2μ , but that in apparently normal adolescent or adult Africans it showed 2 peaks, one at about 7.0μ and the other at about 8.0μ and, though the form of the curve varied in different individuals, these 2 peaks were always present. None of those studied was anaemic, but liver function tests have shown that in such apparently healthy subjects hepatic function was defective. The rare African with normal liver function was, however, found to have a normal Price Jones curve.

A study of the Price Jones curves in patients of all ages with kwashiorkor showed every curve to have 3 peaks, at about 7.0 , 8.0 and 9.0μ , though the actual shape of the curve varied in different individuals. At the same time the peripheral blood showed 3 types of red cell, normocytes, macrocytes and even larger cells for which there is no name, and which were thought to be derived from the intermediate erythroblasts known to be present as well as normoblasts and macroblasts in the bone marrow of such patients. The view is expressed that kwashiorkor is only the acute, final stage of pre-existent, chronic malnutrition, of which the first stage is associated with a dimorphic, and the last with a trimorphic, blood picture.

L. Wills.

2310

FRONTALI, G. "Kwashiorkor o distrofia farinacea"? ["Kwashiorkor or flour dystrophy"?] *Rev. española Pediat.*, 1953, **9**, 657–666. [Clin. Pediat., Univ. Rome.] French, English and German summaries.

A comparative study was made of kwashiorkor, as described in tropical regions of Africa, Asia and Central America, and "flour dystrophy", as it occurs in Italy, Germany, Spain and Greece in districts where supplies of milk are scanty. Apart from the depigmentation, which is prominent in the coloured races but less evident in the white, the clinical signs are similar in the two conditions; retardation of growth in height, rapid oscillations in weight due to fluid changes, dystrophic oedema not connected with renal or cardiac lesions, fermentative dyspepsia with reduced amylolytic capacity, hepatic steatosis, and reduction of blood protein with inversion of the albumin:globulin ratio. The condition is found in rapidly growing subjects, particularly in infants at weaning, when the diet is predominantly farinaceous and lacking in animal protein. In patients with flour dystrophy studied by the author the accompanying signs of different vitamin deficiencies could, without effect

on the general picture, be eliminated by giving the appropriate nutrient. The general condition improved rapidly after the giving of animal protein as skimmed milk, Finkelstein's albuminous milk, or transfusions of plasma.—M. B. Richards.

DE FRANCISCIS, P. and LAMPITELLA, P. Rapporti dietetici nelle collettività manicomiali. [Reports on the diet in mental institutions.] *Boll. Soc. ital. Biol. sper.*, 1953, **29**, 260-263. [Ist. Fisiol., Univ. Naples.]

It had been found previously that the concentrations of pyruvic and lactic acid were abnormally high in the cerebrospinal fluid of mental patients because of insufficient intake of vitamin B₁ (Abst. 4056, Vol. 21). A survey was therefore made of the diet of 1000 patients in the Psychiatric Hospital of Aversa on 84 days, representing one week each month for a year. The average daily consumption of 30 foods is tabulated with a computation of the nutrients. The average diet supplied daily Cal. 2458, fat 48.5 g., carbohydrate 412 g., protein 87 g., Ca 0.67 g., P 1.1 g., Fe 47 mg., vitamin A 3123 I.U., vitamin B₁ 919 µg., riboflavin 964 µg., and vitamin C 37.5 mg. The diet was improved, especially in vitamins, and 3 months later estimation of pyruvic and lactic acids in the blood and cerebrospinal fluid of 10 of the patients yielded values which were normal or much more nearly so than had originally been found.—E. M. Hume.

Vitamin A

2315

STUDNITZ, G. v. Zur Steigerung der Dunkeladaptation durch Helenien und Vitamin A-Emulsionen. [Increase in dark adaptation by means of helenien and vitamin A emulsions.] *v. Graefes Arch. Ophthalmol.*, 1953, **154**, 137-141. [Bad Schwartau.]

The failure of Gleys *et al.* (Abst. 3467, Vol. 23) to confirm that helenien and vitamin A improve dark adaptation is criticised on several grounds, among others that the number of volunteers examined was small and the apparatus used inadequate.

T. Moore.

2316

HAUBOLD, H., LOEW, W. and KOLB, E. Einwirkung von Penicillin auf den Vitamin A-Gehalt des Serums sowie auf die Nachsichtigkeit. [Action of penicillin on the vitamin A content of the serum and on night vision.] *Münch. med. Wochenschr.*, 1953, **95**, 792-796. [St. Pauls-Platz 9, Munich 15.]

Vitamin A was estimated in the blood serum of 5 healthy men aged from 25 to 53 years before and after from 2 to 4 injections of Procaine penicillin, totalling from 800,000 to 1,600,000 I.U., and in the blood of another 5 after 5 injections within 2 days of 200,000 I.U. pure penicillin. The serum value for vitamin A fell rapidly from normal values of well over 100 I.U. per 100 ml. to values below 70 and sometimes as low as 30. In young subjects the value soon tended to rise again without assistance but, usually, as soon as the result was established, the subject received from 50,000 to 600,000 I.U. vitamin A, which restored the blood value and relieved the diarrhoea, circulatory disturbances and feelings of fatigue and incapacity which had been produced in the older subjects. A few subjects with abnormally low blood values were tested, but no fall occurred with penicillin.

In some of the subjects dark adaptation was tested by the method of Engelking and Hartung, and was found to deteriorate after administration of penicillin.—E. M. Hume.

2317

LAURENCE, P. A. and SOBEL, A. E. Changes in serum vitamin A level during the human menstrual cycle. *J. Clin. Endocrinol.*, 1953, **13**, 1192-1200. [Dept. Biochem., Jewish Hosp., Brooklyn 16, N.Y.]

Vitamin A was estimated daily by chemical methods in the blood serum of 6 women who had no history of menstrual disorder. Three of the women were given massive doses of vitamin A some weeks before the observations were started. In 2 of them estimations were made during only one menstrual cycle, in 3 during 2 cycles, and in one

N.A. and R., April 1954

during 6 cycles. The value for the vitamin tended to be low, average 30 $\mu\text{g.}$ per 100 ml., during menstruation and to rise to a maximum value of 75 on the 14th day of the cycle, and again to 70 on the 25th day. The preliminary treatment with vitamin A had no obvious effect on the serum values. In 2 subjects with abnormal menstrual cycles only irregular variations in the vitamin A were observed.—T. Moore.

2318

GRIESEMER, R. D., FRAZIER, C. N. and BLANK, I. H. **Nutritional influences on the physiology of the skin: observations on the metabolism of vitamin A.** *Medicine, Baltimore*, 1953, **32**, 293-321. [Dept. Dermatol., Harvard Med. Sch., Boston, Mass.]

Most of this interesting review is devoted to the general physiology of vitamin A. The topics covered include the measurement of vitamin A, its absorption, fate in the body, rate of utilisation, effect of stress on requirement, functions in the retina and elsewhere, relationship to thyroxine, deficiency in human beings, level in the blood serum, tolerance tests and vitamin A excess. Reference is made also to unpublished work at Massachusetts General Hospital on the value of vitamin A in the treatment of skin diseases. In agreement with previous claims by several workers, massive doses of vitamin A were found to be beneficial, but not completely curative, in Darier's disease and ichthyosis, but to be ineffective in acne vulgaris and psoriasis.—T. Moore.

2319

JAMES, W. H. and ELGINDI, I. M. **Effect of strenuous physical activity on blood vitamin A and carotene in young men.** *Science*, 1953, **118**, 629-630. [Dept. Agric. Chem., Louisiana Agric. Exp. Stat., Baton Rouge.]

Samples of blood for estimation of vitamin A and carotene were taken from 12 members of an athletic team before and after 50 minutes of strenuous physical activity and from 2 controls who remained seated during that time. The vitamin A in $\mu\text{g.}$ per 100 ml. ranged from 25.2 to 55.9 before exercise and from 43.7 to 69.1 after it. The values for the controls were 61.7 and 95.8 before and 73.3 and 92.0 after the same interval. The carotene values for those taking exercise ranged from 63.1 to 154.4 $\mu\text{g.}$ per 100 ml. before, and from 57.5 to 141.0 after, exercise. The corresponding day values for the controls were 94.6 and 143.4 before, and 109.3 and 133.7 after, the interval. The average increase in the vitamin A value during exercise was 47 per cent. with individual changes ranging from an increase of 106 per cent. to a decrease of 22 per cent. The average carotene

value decreased by 9 per cent. with individual changes ranging from +17 to -50 per cent.

GOUNELLE, H., TEULON, H. and CHEROUX, R. Absence d'action hypotensive de la vitamine A synthétique. [**Absence of hypotensive action of synthetic vitamin A.**] *C.R. Soc. Biol.*, 1953, **147**, 1018.

The fall in blood pressure which has been reported in hypertensive patients after the injection of synthetic vitamin A could be produced equally well by injection of the solvent used to carry the vitamin. It is presumed that the local reaction at the site of the injection provoked hypotensive activity in the adrenal glands.

POMERANZE, J. and LUCARELLO, R. J. **Tocopherol response curves and fat absorption.** *J. Lab. Clin. Med.*, 1953, **42**, 700-704. [Dept. Med., Med. Coll., New York.]

Tocopherol was estimated in the plasma of 12 normal adults on a diet low in fat, after fasting, and 3, 6, 9, 12, 24 and 48 hr. after a single dose of 1500 mg. tocopherol in an aqueous or an oily medium. In another experiment the tocopherol was given with a breakfast high in fat. Serum values after fasting ranged from 0.35 to 1.48 mg. tocopherol per cent. The maximum average value attained with aqueous dispersions was 2.5

mg. per cent. after 6 hr.; with the oily medium the maximum was 2.1 mg. after 12 hr. The maximum individual value observed with the aqueous medium was 3.11 mg. per cent. after 6 hr. and with the oily medium 3.08 after 12 hr. Subjects with a previously flat curve of response to tocopherol showed no additional response when fat was given, but those whose absorption was good responded with higher tocopherol values when fat was given. Subjects who had been on a low fat intake before and during the test period had low fasting values for tocopherol and the dose when administered in oil produced a very small response; absorption was better when tocopherol was given to them as an aqueous dispersion. Administration of the test dose with a fatty meal significantly increased the response in these patients.

GOUNELLE, H., MARNAY, C. and BLONDIN, M. L'épreuve d'hypervitaminémie chez le sujet normal. Différence d'absorption de l' α -tocophérol libre et de l'acétate de tocophérol. [Test of high blood vitamin value in the normal human subject. Difference in absorption between free α -tocopherol and tocopheryl acetate.] *C.R. Soc. Biol.*, 1953, 147, 1019-1021. [Centre Recherches Foch.]

When vitamin E was estimated in the blood of 15 normal human subjects before and 6 hr. after ingestion of 2 g. tocopheryl acetate the average increase was 36.3 per cent. When 11 patients without defective absorption were given 2 g. α -tocopherol alcohol the average increase was 118 per cent. In 5 subjects who were given first tocopheryl acetate and one month later free α -tocopherol the increases caused by the alcohol were 3 times as great as those caused by the acetate.

ROSENKRANTZ, H., MILHORAT, A. T. and FARBER, M. (with MAYRAN, M.) Intestinal absorption of vitamin E preparations in a patient with muscular dystrophy. *Metabolism*, 1953, 2, 556-561. [Dept. Med., Cornell Univ. Med. Coll., New York.]

A woman aged 38, with muscular dystrophy of the facioscapulohumeral type, was kept in hospital for a year as a volunteer for experiments on the absorption of α -tocopherol and its derivatives. There was no evidence that the absorption of these substances was impaired, and a sick subject was chosen only because no healthy person would willingly undergo the long stay in hospital. The diet was kept rigidly constant with a tocopherol content of 7.2 mg. daily, and supplementary amounts of 10 mg. natural tocopherols were provided continuously. During periods of 5 to 8 days additional massive doses of tocopherol or

derivatives were given, and the efficiencies of absorption were studied by examination of the faeces. Estimations were made by the ferric chloride method before and after refluxing the extract with HCl and stannic chloride, which had the effect of reducing and cyclising α -tocopherylhydroquinone into α -tocopherol.

When 3.0 g. tocopherol was given over a period of 8 days about 50 per cent. was recovered from the faeces. Only about 25 per cent. was recovered when 0.6 g. tocopherol was given over 6 days with a sorbitan fatty acid ester as emulsifier. Of amounts of α -tocopherylhydroquinone totalling 3 g. in 5 days about 50 per cent. was absorbed. The reading on the faecal extract was about 20 times greater after refluxing than before. Only about 15 per cent. of 1.0 g. of α -tocopherylhydroquinone diacetate, given over 7 days, was excreted, and the addition of the sorbitan emulsifier in a similar experiment reduced the excretion to 10 per cent. After large amounts had been taken tocopherol was passed in small amounts, not exceeding 0.9 mg. daily, in the urine.—T. Moore.

BLONDEL, A., CHUNG, D. V., NHI, N. T. and HUONG, B. Q. Le bérubéri au Nord-Vietnam. Les signes de début. [Beriberi in northern Viet Nam. Initial signs.] *Presse méd.*, 1953, 61, 1312-1314.

The onset of the classical signs of beriberi, polyneuritis, oedema and cardiac failure, is usually sudden and once developed they are often severe and resistant to treatment. Early diagnosis is therefore extremely important and is based on subjective and trivial symptoms, such as lassitude, asthenia, fatigability, palpitations, and occasionally "barre épigastrique" with violent pain which though rare is diagnostic when present. Slight changes in both sensory and motor functions may be present especially in the lower limbs. The

N.A. and R., April 1954

most important objective sign is pseudohypertrophy of the calf muscles, which is concealed when oedema develops. Diagnosis is difficult but the immediate response to treatment with vitamin B₁ will confirm the clinical diagnosis.—L. Wills.

BENCHIMOL, A. B. and SCHLESINGER, P. **Beriberi heart disease.** *Amer. Heart J.*, 1953, **46**, 245-263. [Hosp. Serv. Estado, Rio de Janeiro.]

Over 3 years, 22 cases of heart disease due to beriberi were seen; all the patients were men, all were heavy drinkers and only about half had a history of an associated dietary deficiency. Owing to the high energy intake from alcohol, all the patients appeared to be well nourished and with the exception of 6, all were engaged on very heavy work. Oedema of the lower extremities was the most constant finding and was the initial sign in 14 patients. Dyspnoea of varying degree occurred some time during the course of the disease; signs of pulmonary congestion were present in 19 patients. The signs and symptoms were indicative of left ventricular failure. Ascites was present in 5 patients and the liver was enlarged in all. Both pulse rate and blood pressure varied from patient to patient, and during the course of the disease transient bradycardia might occur during heart failure. Polyneuritis, never severe, occurred in 20 patients. In most of the patients X-ray examination showed enlargement of the heart but, unlike the findings in oriental cases, there was left ventricular enlargement as well as signs of pulmonary congestion, and in only 1 patient was right-sided enlargement predominant. On treatment with vitamin B₁ the size of the heart decreased and in most patients became normal. The electrocardiogram showed nonspecific abnormalities indicating myocardial damage; they cleared up after treatment with vitamin B₁.

HAWTHORNE, B. E., WU, M. L. and STORVICK, C. A. **Thiamine metabolism of women on controlled diets. 3. Daily pyruvic acid values of whole blood.** *J. Clin. Nutr.*, 1953, **1**, 393-394. [Nutrit. Res. Lab., Sch. Home Econ., Oregon State Coll., Corvallis.] Spanish summary.

For previous parts see Abst. 2219, Vol. 23.

Estimations were made daily of pyruvic acid by the micromethod of Tsao and Brown (Abst. 1368, Vol. 20), and of vitamin B₁ in the fasting blood of

Vol. 24, No. 2

4 women receiving a controlled diet containing for 7 days 500 µg. vitamin B₁ per 1000 Cal. and for 14 days 300 µg. per 1000 Cal.

In each woman, when the vitamin B₁ intake was decreased, there was an average increase of from 2 to 11 per cent. in blood pyruvic acid and a corresponding decrease of 11 per cent. in blood vitamin B₁. The changes were significant.—V. R. Jackson.

2331

TURNOCK, D. M. and WELBOURN, R. B. **The effects of glucose on blood pyruvic acid levels in mild thiamine deficiency.** *J. Lab. Clin. Med.*, 1953, **42**, 261-268. [Dept. Surg., Univ. Liverpool.]

Pyruvic acid was estimated by the method of Friedemann and Haugen (Title 16, Vol. 13) in the blood of 32 subjects suspected of mild or chronic vitamin B₁ deficiency. Subjects were fasted for 10 hr., which included an hour's rest, before receiving 100 g. glucose. Blood was taken after 1, 2 and 3 hr., all exercise and tourniquets being avoided.

The basal and peak values for pyruvic acid were normal in all but one subject, but some values failed to return to normal within 3 hr. There was no correlation between the pyruvic acid and blood glucose curves in the subjects concerned, and no undue secretion of adrenaline could be detected.

Eighteen subjects received 10 or 25 mg. vitamin B₁ 3 times daily for from 1 to 12 months and the effect on the blood pyruvic acid curve was compared with that for 20 subjects receiving no treatment. Vitamin B₁ had no effect on the basal value but did reduce the peak value and the extent to which the pyruvic acid value fell after the peak. The difference between the basal value and that reached after from 2 to 3 hr. tended to be greater in those not receiving the vitamin. It is concluded that failure of the pyruvic acid value to return to the basal level within 3 hr. represented a state of vitamin B₁ deficiency.

The test confirmed a clinical diagnosis of deficiency in 8 of 10 subjects, and gave evidence in 7 of 22 others where it was not expected.

BORIĆ, D. **[Contribution to the solution of the pellagra problem and the pellagra picture in the Kosovo-Metohija region.]** *Serb. Acad. Sci., Monogr.* 208, *Sect. Med. Sci.*, No. 5, 1953, pp. 66. [Inst. Nutr., Serbian Acad. Sci., Belgrade.] In Serbian: English summary.

The Institute of Nutrition has been studying pellagra in the region of Kosovo-Metohija, which is racially and religiously varied and culturally backward. The food of the region is poor, largely maize bread, and pellagra is endemic. The traditional food habits are deeply rooted. In the years

1949-52, 4443 persons were examined and 1185 had pellagra. Men, women and children, and the two races, Serbs and Shiptars, are affected, Shiptars more often than Serbs. Adults fall ill most usually between 40 and 50 years of age, children between 10 and 15 years. The average daily intake of protein is 50.8 g., with 15.8 g. of animal origin. The disease is often chronic and not severe, without mental changes, but there are patients who are mentally affected. Signs of other deficiencies, such as pericorneal injection and hemeralopia, may be present also, and the author considers that riboflavin deficiency frequently accompanies pellagra. Retardation of growth in children is serious. Anaemia and goitre occur. The typical changes are described and illustrated in 69 excellent plates, 27 of them coloured.

When treatment was given, it suggested that the deficiency was multiple. In the village of Prilike in another region where pellagra does not occur, the diet contains much maize, but the protein supply is much better. (From summary.)

DOTTA, F. and CAMPANA, C. Eliminazione urinaria di acido nicotinico, nicotamide e loro derivati N₁-metilati nell'uomo sano e nel ratto albino trattati con isoniazide. [Excretion in the urine of nicotinic acid, nicotinamide and their N¹-methylated derivatives in healthy man, and in the rat, treated with isoniazide.] *Acta vitaminol.*, 1953, 7, 189-193. [Ist. Clin. Med., Univ. Rome.] English, French, German and Spanish summaries.

Three normal male subjects, aged from 25 to 35 years, were maintained on a low ration of tobacco and a constant mixed diet with exclusion of coffee, chocolate and pulses. Isoniazide (isonicotinic acid hydrazide) was given in an oral dose of 4 mg. per kg. bodyweight daily for 12 days. Nicotinic acid and amide, and trigonellin by the method of Roggen, were estimated in the urine daily throughout and for 7 days beforehand and for 5 days afterwards. No consistent change occurred. The results were confirmed with rats.—E. M. Hume.

2334

ROSENTHAL, H. L., GOLDSMITH, G. A. and SARETT, H. P. Excretion of N¹-methylnicotinamide and the 6-pyridone of N¹-methylnicotinamide in urine of human subjects. *Proc. Soc. Exp. Biol. Med.*, 1953, 84, 208-211. [Div. Nutrit., Dept. Med. Sch. Med., Tulane Univ., New Orleans, La.]

Adult human subjects, aged from 25 to 57, were maintained on diets containing high proportions of maize or wheat as previously described (Abst. 856, Vol. 23), supplying daily from 4.3 to 6.0 mg. nicotinamide and from 180 to 230 mg. tryptophan.

In the urine N¹-methylnicotinamide and pyridone were estimated fluorimetrically, creatinine by the alkaline picrate method, and N by Kjeldahl's method.

The average daily amounts excreted were 2.9 mg. N¹-methylnicotinamide and 4.7 mg. pyridone. After an oral test dose of 50 mg. nicotinamide there was in the ensuing 24 hr. an average increase in excretion of 5.5 mg. N¹-methylnicotinamide and of 23.4 mg. pyridone. The increase in excretion of the former was rapid during the first 4 hr.; that of pyridone was slower and less was excreted in the first 4 hr. than in the following 20 hr.

Three normal women and 2 with pellagra received a diet containing twice as much nicotinamide and 5 times as much tryptophan as the diets described above, and, at intervals of 3 days, a test dose of 10, 25 or 50 mg. nicotinamide. The average daily excretion of the normal subjects on the basal diet was 4.2 mg. N¹-methylnicotinamide and 5.9 mg. pyridone, and of the pellagrous subjects 1.3 and 0.9 mg., respectively. After 10 mg. nicotinamide, normal subjects excreted slightly more N¹-methylnicotinamide and 5 mg. more pyridone; after the higher doses excretion of both increased significantly. In the pellagrins excretion of both substances was much less than normal after 10 and 25 mg., but after 50 mg. the values were like those of normal subjects.—V. R. Jackson.

IAKUSHEVA, I. V. Vliyanie nikotinovoi kisloty na kharakter pletizmograficheskoi krivoi. [Effect of nicotinic acid on plethysmograph curve.] *Klin. Med., Mosk.*, 1952, 30, No. 8, 78-81. [Kaf. Terapii Leningrad. Inst. Usovershenstvovan. Vrach.]

When nicotinic acid was given intravenously two phases could be distinguished, a short phase lasting up to 30 sec. during which the plethysmograph curve fell and its oscillation decreased, and a second phase lasting from 5 to 7 min. during which the plethysmograph curve rose again and there was increased oscillation. The results suggested that nicotinic acid acts on the central nervous system, particularly the vascular and respiratory centres. (From summary.)

KROTOVA, M. I. Lechenie nikotinovoi kislotoi narushenii slukhovoii funktsii y lits rabotayushchikh na shumnykh proizvodstvakh. [Treatment with nicotinic acid of disturbances of auditory function in persons working in noisy factories.] *Vestn. Otorinolaringol.*, 1952, No. 2. 35-38. [Kaf. Bolesn. Ukha. Gorlainosa. Voenn.-Morsk. Med. Acad.]

Thirty people, 28 men and 2 women, 26 of them between 30 and 50 years and 4 over 50, who worked in noisy factories were given a course of 3 injections of nicotinic acid weekly for 5 weeks (20 to 50 mg. according to the patient's reaction). Hearing improved in 22; no change was produced in the other 8. Of 20 who complained of noise in the ears, 2 observed that the noise had disappeared after the course and 6 that it had decreased; there was no change in the others. The general state of health improved during the treatment. The improvement in hearing was maintained 2½ months after the course. The beneficial effect of nicotinic acid is probably related to expansion of the blood vessels to the ear.—W. Hughes.

WU, M. L., WARREN, E. and STORVICK, C. A. Riboflavin metabolism of women on controlled diets. *J. Nutrition*, 1953, 51, 231-239. [Nutrit. Res. Lab., Sch. Home Econ., Oregon State Coll., Corvallis.]

During periods of 34 and 30 days, 7 normal women aged from 24 to 44 received a controlled diet providing daily 2000 Cal. and 1.2 mg. riboflavin.

The average daily urinary excretion ranged from 315 to 467 µg. riboflavin, representing from 27 to 40 per cent. of the intake. In the second period there was a continual decrease in riboflavin excretion, which suggested that the food intake before this test period supplied more vitamin than the controlled diet. One subject showed peak levels of excretion after attacks of migraine.

Daily creatinine excretion ranged from 248 to 474 µg., but in the last 10 days of the second period values for 2 subjects fell below 200 µg. which, according to Aykroyd *et al.* (Abst. 2612, Vol. 19), was a sign of inadequate riboflavin intake. These 2 subjects were bigger than the others.

In µg. per 100 ml. the average content of total riboflavin in the serum was 3.21, range from 1.72 to 6.25, and of free riboflavin 1.41, range from 0.21 to 4.23. Average fasting values for 29 normal adults were 2.89 and 1.01.

Two weeks after the second period a test dose of 2 mg. riboflavin was given; free and total serum riboflavin reached a peak within an hour and fasting values were regained after 2 and 5 hr., respectively. The maximum urinary excretion was reached in 1 hr. and the fasting value in 5 hr.

VILTER, R. W., MUELLER, J. F., GLAZER, H. S., JARROLD, T., ABRAHAM, J., THOMPSON, C. and HAWKINS, V. R. The effect of vitamin B₆ deficiency induced by desoxypyridoxine in human beings. *J. Lab. Clin. Med.*, 1953, 42, 335-357. [Dept. Int. Med., Coll. Med., Univ. Cincinnati, Ohio.]

Clinical signs of vitamin B₆ deficiency, including anorexia, nausea, listlessness, seborrhoeic dermatitis, cheilosis, conjunctivitis, glossitis, pellagra-like dermatitis and polyneuritis, appeared in 34 of 50 patients who voluntarily took from 50 to 500 mg. desoxypyridoxine daily with a normal hospital diet or with one lacking in the vitamin B complex. Blood studies were made on 18 patients; lymphocytopenia occurred at the time of development of severe skin lesions. Mild anaemia in 5 patients appeared not to be related to lack of vitamin B₆. Metabolism studies showed an abnormally high excretion of xanthurenic acid after administration of tryptophan, high urea excretion in fasting subjects, and raised blood urea after ingestion of alanine. All the metabolic changes were corrected

and the skin lesions were healed after administration of pyridoxine, pyridoxal or pyridoxamine. Application of ointment containing vitamin B₆ to the skin lesions cured the immediate skin condition and, if widely applied, it cured the general symptoms too.

The results demonstrate that man needs vitamin B₆, and a daily intake of from 2 to 3 mg. is suggested as sufficient for the normal requirement.

2342

MAGGIONI, G. and ASSENSIO, A. M. Eliminazione urinaria di acido xanturenico dopo carico orale di triptofano in varie condizioni patologiche del bambino. [Urinary excretion of xanthurenic acid by children after oral administration of tryptophan in various pathological conditions.] *Arch. ital. Pediat. Puericolt.*, 1953, 16, 43-62. [Ist. Clin. Pediat., Univ. Rome.] French, English and German summaries.

The xanthurenic index of Chiancone (Abst. 2673, Vol. 21; Title 1192, Vol. 22) relates the amount of xanthurenic acid excreted in the urine to the amount of tryptophan given as a test dose. It should not exceed 1. High values are regarded as evidence of vitamin B₁ deficiency.

In the urine of 16 children with different diseases, aged from 39 days to 11 years, xanthurenic acid was estimated by a method depending on the green colour produced by it in presence of ferrous sulphate, after administration of a dose of tryptophan, usually of 50 mg. per kg. bodyweight. Six of the children excreted no xanthurenic acid after the test dose. In the remaining 10 the xanthurenic index ranged from 0.25 to 9.6, with only two values of less than 1. The size of the index bore no relation to the nature of the disease. On intramuscular injection of 50 mg. vitamin B₆ at the same time as the dose of tryptophan, xanthurenic acid disappeared from the urine of 9 of the children. In the tenth the index was reduced from 9.6 to 1.99.

NICHELE, G. and ROVELLI, G. Studi sui metaboliti del triptofano. 2. Ricerche sulla eliminazione urinaria di acido nicotinico e trigonellina nel bambino dopo prove di carico con triptofano e vitamina B₆. [Studies on tryptophan metabolites. 2. The urinary elimination of nicotinic acid and trigonellin in children after a test dose of tryptophan and vitamin B₆.] *Arch. ital. Pediat. Puericolt.*, 1953, 16, 129-150. [Ist. Clin. Pediat., Univ. Rome.] French, English and German summaries.

Nicotinic acid and trigonellin were estimated in the urine of 15 of the children in the experiment described in the preceding Abst. In the 48 hr.

after administration of tryptophan there was a marked increase in the amount of nicotinic acid and of trigonellin excreted by all except one child, a different child in each case. After administration of vitamin B₆ with the tryptophan to 12 of the children, the amount of nicotinic acid excreted was even greater in 8, but in 4, although there was an increase, it was less than with tryptophan alone. With trigonellin also, the response to tryptophan and vitamin B₆ was sometimes greater and sometimes less than to tryptophan alone. The amounts of nicotinic acid and trigonellin excreted did not seem to bear any relation to one another.

SPRAY, G. H. and WITTS, L. J. The utilisation of folic acid in anaemia and leukaemia. *Clin. Sci.*, 1953, 12, 385-390. [Nuffield Dept. Clin. Med., Radcliffe Infirmary, Oxford.]

The concentration of folic acid in the plasma and the amount excreted in the urine were estimated before and after an oral test dose of 1 mg. pteroylglutamic acid in a series of patients. The values were compared with normal values previously obtained by the same method. In hypochromic anaemia there was apparently normal utilisation of folic acid. The slightly but not significantly lower values in the plasma and urine of patients with haemolytic anaemia suggested the existence of an increased demand. The values were low in patients with pernicious anaemia and in one with scurvy. In leukaemia of both types most patients showed low values for folic acid in the plasma and urine, but in one patient with *polycythaemia vera* they were normal. Since there is no evidence of failure in absorption from the gut in leukaemia, it is suggested that utilisation is increased and that the present findings support the view that the same increase in utilisation occurs in untreated pernicious anaemia.

L. Wills.

2346

SPRAY, G. H. and WITTS, L. J. The utilisation of folic acid injected intravenously. *Clin. Sci.*, 1953, 12, 391-397. [Nuffield Dept. Clin. Med., Radcliffe Infirmary, Oxford.]

Folinic acid was estimated microbiologically and recovery tests showed the method to be satisfactory for folinic acid in plasma. The test dose consisted of 1 mg. folinic acid in 2 ml. normal saline and there were 5 normal subjects, 5 patients with un-

treated pernicious anaemia, 2 with subacute combined degeneration and 1 with steatorrhoea. In all subjects the folinic acid level was high 10 min. after the injection and there was no significant difference between the rate of disappearance from the plasma in normal and sick subjects. Patients with pernicious anaemia and the one with steatorrhoea excreted in the urine less than the normal subjects and the patients with subacute combined degeneration. The folinic acid space, *i.e.*, the total quantity of folinic acid in the body divided by the concentration in the plasma, was significantly greater 10 min. after the injection and greater but not significantly so 90 min. after the injection in the patients with pernicious anaemia and the patient with steatorrhoea than in the normal subjects. It is concluded from these findings that in pernicious anaemia there is an increased demand for folic acid and its derivatives, which was not demonstrable in the study of the plasma figures alone.—L. Wills.

BEGEMANN, H., KEIDERLING and WALTER, F. Der Einfluss der Folsäure auf die Eisenresorption. [**Influence of folic acid on iron absorption.**] *Klin. Wochenschr.*, 1953, **31**, 881–883. [Med. Klin., Univ. Freiburg i. Br.]

Serum Fe was estimated before and 2, 4 and 6 hr. after an oral dose of 200 mg. Fe as ferrous sulphate. The tests were repeated from 4 to 10 days later when 5.1 mg. folic acid were given with the same dose of Fe. Folic acid alone in this amount had no effect on the serum Fe value in 2 subjects with normal initial values or of 3 with low initial values. In 7 subjects with normal values and normal gastric acidity, the addition of folic acid to the dose of Fe did not alter the height of the rise in the serum Fe value, but in 8 subjects with low initial values and normal gastric acidity there was some increase in Fe absorption, though the increase in the rise was not significant. In 13 subjects with low initial values and hypochlorhydria or achlorhydria, the difference was highly significant, the mean rise in those having Fe only being 101 μ g. per cent., and in those having folic acid as well 176. Similar tests in 4 other subjects showed that the use of folic acid with Fe produced a far greater rise than the same dose of Fe with ascorbic acid. The results are discussed.

GIRDWOOD, R. H. Folic-acid-excretion studies in the investigation of malignant disease. *Brit. Med. J.*, 1953, ii, 741–745. [Dept. Med., Univ. Edinburgh.]

Folic acid excretion after a test dose of 5 mg. given parenterally was estimated in a large number of patients with different diseases; an excretion

of less than 30 per cent. of the test dose, *i.e.*, of less than 1.5 mg. in 24 hr., was considered low. In patients without prolonged infection and with no evidence of malignant disease, the results of the test were normal except in those with large effusions or oedema, when the vitamin was present in the effusion fluid. Normal excretion occurred in some patients with malignant disease, but in a large number of them excretion was low; there was no correlation between the amounts excreted and the erythrocyte sedimentation rate or the degree of anaemia. Excretion was low also in some patients with long-standing infection. In patients with megaloblastic anaemia the results were variable.—L. Wills.

2349

THEDERING, F. and RIETHMÜLLER, H. U. Die Behandlung megaloblastischer Anämieformen mit einer Kombination von Vitamin B₁₂ und Formylfolsäure. [**Treatment of megaloblastic anaemia with a combination of vitamin B₁₂ and formylfolic acid.**] *Deutsch. med. Wochenschr.*, 1953, **78**, 1470–1474. [Med. Klin., Univ. Tübingen.]

On the theory that a dual deficiency may exist or develop in megaloblastic anaemia, a trial was made of a preparation containing vitamin B₁₂ and formylfolic acid, a product intermediate between folic acid and the citrovorum factor. Sixteen patients with pernicious anaemia were treated with the combined product in an initial dose containing from 60 to 90 μ g. vitamin B₁₂ and from 20 to 30 mg. formylfolic acid; the dose was repeated every 8 days until a full remission was obtained. In patients with neurological signs the dose was continued for up to 6 months and in severe cases the amount of vitamin B₁₂ was increased to 200 μ g. The mean maintenance dose was 79 μ g. vitamin B₁₂ and 26 mg. formylfolic acid monthly. Fourteen similar patients were treated with vitamin B₁₂ alone for comparison. Both treatments produced satisfactory clinical and haematological remissions and improvement in the nerve signs, but with the combined therapy the size of the mean dose of vitamin B₁₂ and the time required to produce a full remission were both less.

- GILLHESPY, R. O. **The treatment of pernicious anaemia and allied megaloblastic anaemias.** *Practitioner*, 1953, **171**, 648-652. [Haematol. Clin., Dudley Rd. Hosp., Birmingham.]

The haematological response to parenteral administration of crude or purified liver extracts or of vitamin B₁₂ and to oral administration of proteolysed liver was studied in 90 patients with pernicious anaemia. In most of them a satisfactory response was produced by any of the preparations, but some patients could not be maintained in a satisfactory haematological state by certain of the preparations but could by some other, and in certain patients proteolysed liver given orally was the only effective treatment. Megaloblastic anaemia after gastrectomy was successfully treated with liver extract or vitamin B₁₂ given orally, and that associated with pregnancy with folic acid or proteolysed liver given orally.—L. Wills.

- FOY, H. and KONDI, A. **Treatment of megaloblastic anaemias. Relation of penicillin to vitamin B₁₂.** *Lancet*, 1953, **265**, 1280-1285. [Wellcome Trust Res. Labs.]

Response to treatment was studied in 25 Africans with typical megaloblastic anaemia; 16 responded to penicillin given orally or by intramuscular injection, 4 failed to respond to penicillin at all or to vitamin B₁₂ given orally, but responded to it given parenterally, and 4 failed to respond at all to penicillin or vitamin B₁₂ but responded to folic acid given orally. There was histamine-fast achlorhydria in the 4 who responded only to vitamin B₁₂ given parenterally, and in the 2 of them examined atrophic gastritis was found; they were considered to be suffering from pernicious anaemia. The findings and the relevant literature are discussed, and it is suggested that penicillin influences the biosynthesis and utilisation of intestinal vitamin B₁₂ but is inactive in the absence of intrinsic factor.

- MEYER, L. M., BECERRA-GARCIA, A., GOLDMAN, A. and STERN, P. A. **Oral administration of Co⁶⁰ vitamin B₁₂ to normal persons, patients with pernicious anemia, and subjects with various medical disorders.** *J. Appl. Physiol.*, 1953-1954, **6**, 263-268. [Third Med. Serv., Goldwater Mem. Hosp., Brooklyn, N.Y.]

After an oral dose of 1.0 µg. ⁶⁰Co vitamin B₁₂ the total faecal excretion of ⁶⁰Co, expressed as a percentage of the dose, ranged from 8 to 41 in normal subjects; repeat tests on the same subjects showed that an increase up to threefold might occur. Similar tests in patients suffering from a variety of medical conditions showed a range of from 11 to 100 per cent.; there was no relationship between the presence of free HCl in the gastric juice and the amount of ⁶⁰Co excreted in the faeces. Repeat tests showed the same wide variations as in normal subjects. In patients suffering from untreated or treated pernicious anaemia, the values ranged from 48 to 100 per cent.; the addition of 100 ml. normal gastric juice to the test dose reduced the excretion in 5 of 6 patients tested, but the addition of folic acid or intrinsic factor had a variable effect. The wide variation in excretion from subject to subject and in the same subject after repeated doses made it difficult to draw a definite conclusion from these and similar observations.—L. Wills.

GOLDBECK, H. and WEISS, C. Die B-Aktivität im Blutserum nach intravenöser Belastung mit Vitamin B₁₂. [Vitamin B₁₂ activity in the blood serum after intravenous administration of vitamin B₁₂.] *Klin. Wochenschr.*, 1953, **31**, 860-861. [2. Med. Klin., Univ. Hamburg, Eppendorf.]

Free and bound vitamin B₁₂ were estimated microbiologically in serum with *Euglena gracilis* as the test organism for periods of up to 5 days after a single intravenous dose of 90 µg. of the vitamin. In all subjects examined there was an immediate steep rise in the free vitamin content of the serum. In 3 healthy subjects 2 hr. after a rise of about 600 µg. per ml. the value for the free vitamin began to fall and had reached its initial value in about 72 hr. The value for the bound vitamin began to rise when that for the free vitamin began to fall, and 4 hr. later it was above the value for the free vitamin; it continued to rise for another 6 hr. and then fell gradually to its initial value in 144 hr. In 2 Fe-deficient patients there was a similar rise and fall in the value of the free vitamin but the rise was from a high initial value; the value for the bound vitamin remained almost the same throughout the test period. In 2 patients with leucosis and 3 with bronchial carcinoma the value for the free vitamin rose slightly from an initially very low value; within 3 hr. all the vitamin was in the bound form.—L. Wills.

BECKER, B., LANG, C. A. and CHOW, B. F. Vitamin B₁₂ excretion and diabetic retinopathy. *J. Clin. Nutr.*, 1953, **1**, 417-423. [Dept. Biochem., Sch. Hyg. Pub. Health, Johns Hopkins Univ., Baltimore, Md.] Spanish summary.

Preliminary observation had suggested that the urinary excretion of vitamin B₁₂ after a test dose might be low in certain diabetics, so a controlled study was made. After a single intramuscular injection of 50 µg. vitamin B₁₂ the mean amount excreted was 9.6 ± 1.4 µg. by 6 healthy adults, 19.0 ± 2.1 by 22 diabetics with retinopathy and 4.2 ± 1.7 µg. by 13 diabetics without retinopathy. The differences between the 2 diabetic groups and between each of these and the non-diabetic group were significant. Further studies on a group of 11 diabetics with retinopathy showed that the intramuscular injection of from 100 to 200 mg. testosterone every 2 or 3 weeks produced in all of them a fall in the vitamin B₁₂ excretion. In rats given 1 µg. radio-active vitamin B₁₂, the urinary excretion of the vitamin after administration of 5 mg. cortisone daily on 6 days a week for 3 weeks was nearly double that of rats given 1 ml. saline instead of cortisone. In a similar experiment, other rats given 10 mg. testosterone subcutaneously

every day for 2 weeks showed no significant difference in their excretion from rats not given testosterone.—L. Wills.

BAYNE, G. M. and BOGER, W. P. Vitamin B₁₂ supplementation of the diet of healthy adults. A study of weight changes employing a Latin square design. *J. Clin. Nutr.*, 1953, **1**, 424-429. [Dept. Res. Therap., Norristown State Hosp., Pa.] Spanish summary.

A study was made of 44 physically healthy women under observation before discharge from a mental hospital. Every subject received each of 3 treatments for 3 months, and 3 groups were constituted receiving the treatments in varying order according to the Latin square design. The treatments were with 100 µg. vitamin B₁₂ once daily, 30 µg. vitamin B₁₂ three times daily or a dummy tablet. No significant weight gain was attributable to vitamin B₁₂ under the conditions of the test, and no difference appeared between periods in which 100 µg. was taken in tablet form or as an elixir in 3 separate doses of 30 µg. each. No evidence of the effect of vitamin B₁₂ on appetite was derived from the study. In spite of the negative results it is emphasised that, since vitamin B₁₂ is known to have important metabolic effects, it is advisable to include it in multivitamin preparations.—A. M. Copping.

SCRIMSHAW, N. S. and GUZMÁN, M. A. Efecto de los suplementos dietéticos y de la administración de vitamina B₁₂ y aureomicina sobre el crecimiento de los niños de edad escolar. [Effect of dietary supplements and of the administration of vitamin B₁₂ and aureomycin on the growth of children of school age.] *Bol. Ofic. sanit. panamer.*, 1953, **34**, 551-562. [Inst. Nutric. Centro America y Panamá, Guatemala.]

A survey of schoolchildren aged from 7 to 11 years in urban and rural areas of El Salvador and Guatemala showed that those in the lower income groups were retarded in height and in weight in comparison with those of children in the United States. The diets were low in animal protein, vitamin A, Ca and riboflavin. A very high incidence of infestation with intestinal parasites was found. Supplements of animal or vegetable protein were given to groups of from 12 to 80 children in the form of ice-cream made from dried milk or soya bean milk. In comparison with children in the same areas having no supplement the additions had no significant influence on height and weight. Addition of vitamin B₁₂ or aureomycin with or without a protein supplement did, however, cause an increase in the coefficient

of height and weight increase. When these supplements were withdrawn, the growth rate was lower.

MALLARDI, A. Sull'impiego di aminoacidi, siero citossico, vitamina B₁₂ in lattanti distrofici, nati da madri tubercolotiche. Nota clinica. [Use of amino-acids, cytotoxic serum and vitamin B₁₂ in dystrophic infants of tuberculous mothers. A clinical note.] *Lattante*, 1953, 24, 307-320. [Preventorio Prima Infanzia Principessa Maria Pia di Savoia, Trani.]

Ten dystrophic children, aged from 4 to 19 months, offspring of tuberculous parents but not themselves affected, were given for 21 days an enzymic protein hydrolysate in an oral dose of 2 g. per kg. bodyweight daily. There was general clinical improvement with accelerated weight gain, more red cells and a higher percentage of Hb. Cytotoxic serum (anti-reticulo-endothelial serum, Citolisina (Sclavo)) was given to another 6 dystrophic children of the same type in 4 injections of 0.1, 0.2, 0.3 and 0.4 ml. at intervals of 4 days. Four were watched subsequently for about 3 months. Some improvement was observed and no adverse effect, but it is considered that the preparation should be used with great caution. Another group of 10 similar children received daily for a month a parenteral dose of 10 µg. vitamin B₁₂. Results were not dramatic but there was accelerated weight increase in all but 3 babies, with improvement in general condition, in number of red cells and in Hb percentage.—E. M. Hume.

MEYER, L. M., SUAREZ, R. M. (Jr.), BUSO, R., SABATER, J. and SUAREZ, R. M. Oral administration of Co⁶⁰ vit. B₁₂ in tropical sprue and hepatic cirrhosis and diarrhoea. *Proc. Soc. Exp. Biol. Med.*, 1953, 83, 681-683. [Labs. Fund. Invest. Clin., Santurce, Puerto Rico.]

Under the experimental conditions 4 normal subjects excreted in the faeces from 31 to 78 per cent. of the ⁶⁰Co contained in a standard oral dose of 0.5 µg. ⁶⁰Co vitamin B₁₂ given fasting in 250 ml. water. In 5 with tropical sprue, 4 of them with free gastric HCl and one with achlorhydria, and in 1 with cirrhosis and diarrhoea, the excretion after the same dose showed a similar range; repeat tests either with addition of folic acid to the test dose or after administration of folic acid for different periods showed no consistent change in the excretion of ⁶⁰Co.—L. Wills.

BANERJEE, S. and BELAVADY, B. Dehydro-ascorbic acid level of blood in health and in typhoid fever. *Lancet*, 1953, 265, 912-913. [Dept. Physiol., Presidency Coll., Calcutta.]

Blood from 21 normal persons contained on the average, per 100 ml., 0.88 ± 0.03 mg. ascorbic acid and 0.09 ± 0.1 mg. dehydroascorbic acid. The figures for 41 persons with classical signs and symptoms of typhoid fever were 0.54 ± 0.06 and 0.27 ± 0.03 ; for 11 convalescents the values were 0.72 ± 0.001 and 0.16 ± 0.003 .—W. Godden.

2366

BRONTE-STEWART, B. The anaemia of adult scurvy. *Quart. J. Med.*, 1953, 22, 309-329. [Dept. Med., Univ. Cape Town.]

A study was made of 32 adult males, 31 of them Bantu, aged from 22 to 60 years, with typical scurvy; 13 of them were studied in detail. They were maintained on the diet on which they had developed scurvy and during periods of varying length different patients received vitamin B₁₂ parenterally, folic acid orally, Fe intravenously, vitamin B complex parenterally, and other substances such as cortisone in therapeutic doses; later each received 1000 mg. vitamin C daily, intravenously. Full diet was not given until the packed cell volume was over 40 per cent. In over 80 per cent. of the patients the mean cell volume was below 40 per cent. on admission and in most of them the anaemia was severe. The anaemia was generally normocytic and normochromic but in the severe cases it was macrocytic and in one it was megaloblastic. There was marked anisocytosis. The reticulocyte count might be raised and after rest in bed it rose. The platelet count, and the bleeding, coagulation and prothrombin times were within the normal range. The bone marrow was hypercellular but mitotic figures were reduced in number.

There was no response to the haemopoietic substances tested, but when vitamin C was given the bone marrow showed intense activity and the peripheral reticulocyte count rose. Histamine-fast achlorhydria and hypochlorhydria were common, but peptic activity was normal. Low plasma Fe and Fe-binding capacity were associated with the presence of haematomas, and increased excretion of pigment was related to extravascular haemolysis in haematomas. There was definite improvement in the scorbutic condition after rest in bed, but neither rest nor the administration of

N.A. and R., April 1954

blood-forming substances produced any significant improvement in the blood picture.—L. Wills.

2367

MERSKEY, C. **Survival of transfused red cells in scurvy.** *Brit. Med. J.*, 1953, ii, 1353-1356. [Dept. Med., Univ. Cape Town.]

In 8 adult males, 7 Bantu and 1 Indian, with scurvy and normoblastic anaemia, and in 1 Bantu with scurvy but not anaemia, the survival time of transfused red cells was measured while the patients were at rest in bed on a diet lacking vitamin C. The survival time was reduced in 6 of the 9 patients; in 2 it appeared normal, but they were only observed for a short time, and in the remaining subject the transfused red cells disappeared rapidly after treatment with vitamin C. In the 6 patients with reduced survival time, administration of vitamin C caused an immediate reduction in the rate of destruction in 3, but in 2 the reduction occurred only after 2 or 3 days' treatment, and in the sixth patient, who had bled severely after administration of cortisone, the accelerated blood destruction continued for from 9 to 10 days after vitamin C treatment began. In a further study 3 very anaemic, scorbutic Bantu patients showed the same rapid destruction of transfused red cells; 6 less severely anaemic subjects had 1 pint of blood removed before receiving a transfusion of the same amount of blood, and here again the transfused cells were very rapidly destroyed in 4 anaemic and 1 non-anaemic patient, but in the one remaining patient, who was not anaemic, the survival time was normal. The addition of protein to the scorbutic diet did not alter the red cell survival time. The findings are considered evidence of the presence in these patients of a haemolytic process which must be important in producing the anaemia of scurvy.—L. Wills.

CAJANDER, B. **Observations on a cortisone-like effect on injection of desoxycorticosteronacetate (DOCA) in combination with ascorbic acid in rheumatic diseases.** *Acta med. scand.*, 1953, 147, 53-59. [Dept. Med., Garrison Hosp., Boden, Sweden.]

A series of 65 patients with rheumatoid conditions, including 45 with classical rheumatoid arthritis, were treated with a total daily dose of 10 mg. desoxycorticosterone acetate and 2 g.

Vol. 24, No. 2

ascorbic acid, given parenterally for 10 days; the treatment was repeated after from 7 to 10 days in some patients. The results varied but in 33 per cent. of the male, and 55 per cent. of the female, or 49 per cent. of all, with rheumatoid arthritis there was both subjective and objective improvement, and similar results were obtained in the other patients. The remainder were unchanged or deteriorated. Those who improved showed the greatest weight gain; the erythrocyte sedimentation rate rose in all patients who deteriorated and frequently fell in the patients who showed improvement. The differences in response were attributed to differences in hormone balance.

HINES, L. E., CATLIN, J. and KESSLER, D. L. **Tests for so-called capillary fragility of the skin and the significance of positive tests in vascular disease.** *Amer. J. Med.*, 1953, **15**, 175-179. [Northwestern Univ. Dept. Med., Chicago, Ill.]

A negative pressure method was used for capillary fragility tests, which were made on skin in the interscapular region. Tests were positive in 2 of 102 healthy adults under 30 years of age and in 18 of 150 aged from 30 to 80, with normal blood pressure and no signs of vascular disease. In 46 patients with vascular disease but with normal blood pressure there were positive signs in 8, but in 116 patients with hypertension there were positive tests in half. In diabetics the percentage incidence of positive tests was 7 if hypertension was absent but 67 if it was present. In acute myocardial infarction there was no marked difference in the incidence of positive tests between patients with and without hypertension.

ROECKELEIN, R. Ein neues Verfahren zur Messung der Capillarresistenz. [New method of measuring capillary resistance.] *Klin. Wochenschr.*, 1953, **31**, 751-754. [Pathol. Inst., Univ. Bonn.]

The method depended on the production of petechial haemorrhages of the skin in the space within a small circular mouthpiece which was applied to the arm with a progressively increased pressure brought about by compression of a spring. Since the area of the skin affected was very small, repeated trials could be made until the exact pressure was found at which a visible haemorrhage was produced. Measurements were made on 165 healthy persons to establish a normal value for the pressure. The values ranged from 1400 to 2100 g.

ACKERMANN, P. G. and TORO, G. **Effect of added vitamin D on the calcium balance in elderly males.** *J. Gerontol.*, 1953, **8**, 451-457. [Div. Gerontol., Sch. Med., Washington Univ., St. Louis, Mo.]

With the same methods except that for Ca, and with 6 of the same elderly men as were previously studied (Abst. 798, Vol. 24), balances of Ca and P were estimated. A comparison was made of results for Ca in food, urine and faeces obtained with the flame photometer and by a chemical method with precipitation of Ca as oxalate and titration with permanganate. The agreement was very good, and the flame photometer was used for the greater part of the study. Ca and P balances were measured consecutively during 60 days when no vitamin D was given, during 40 days when 25,000 I.U. were given daily, for 40 days in the course of 3 months when no vitamin was given, during 40 days when 600 I.U. daily were given, and during 60 days when 1800 I.U. daily were given. The complete schedule was not carried out with all subjects, particularly in estimations of P. The mean value for each individual for each period was calculated.

All the subjects were in negative Ca balance in the first period without vitamin D and all but one in the second. With 25,000 I.U. daily all were in positive balance or in equilibrium. With 600 or 1800 I.U. daily the results were not consistent, though the average Ca retention was increased.

N.A. and R., April 1954

The P balance was estimated only for the dose of 25,000 I.U., and gave no consistent results.

E. M. Hume.

KALoud, H. and STEUDTE, E. Vergleichende Untersuchungen über die Wirkung der peroralen Stosstherapie mit dem künstlichen Vitamin D₂ und dem natürlichen D₃ bei der Säuglingsrachitis. [Comparative action of single large oral doses of artificial vitamin D₂ and natural vitamin D₃ in infantile rickets.] *Öst. Ztschr. Kinderheilk.*, 1953, 9, 66-75. [Kinderklin., Univ. Graz.]

An X-ray photograph of the wrist and estimations of Ca, inorganic P and alkaline phosphatase in the blood serum were made before, and 6 or more days after, administration of a single oral dose of 15 mg. vitamin D₃ to 16 children with moderate or severe rickets or of vitamin D₂ to 9. The rate of healing of craniotables and the decrease in size of the fontanelle after 4 weeks were superior in the children given vitamin D₃. Other criteria showed no definite difference.—E. M. Hume.

2382

BURGSTEEDT, H., HILBER, H. and SCHEPPE, K. J. Ernährung und Diätetik. Pränatale Rachitisprophylaxe. [Food and dietary treatment. Antenatal prophylaxis of rickets.] *Münch. med. Wochenschr.*, 1953, 95, 938-941. [Kinderklin., Univ. Munich.]

Through the welfare centres of the city of Munich, 97 women, most of them in the fourth month of pregnancy, were given every other day a tin of condensed milk containing 1600 I.U. vitamin D. The distribution was continued until the baby was 3 months old; the mother was told to give it no other source of vitamin D until that age. The observations lasted 2 years from March 1950.

Of the 97 infants, 70 were without radiographic rickets in the first 3 months of life, while of 97 similar infants whose mothers had been untreated but were themselves given vitamin D, only 47 were without radiographic rickets in the first 3 months. It is therefore recommended that there should be antenatal as well as postnatal prophylaxis of rickets.—E. M. Hume.

2383

RUZICZKA, O. Klinische Untersuchungen bei Vitamin-D-Überdosierung. [Clinical investigation of vitamin D overdosing.] *Öst. Ztschr. Kinderheilk.*, 1953, 9, 4-21. [Kinderklin., Univ. Vienna.]

A full account is given of the clinical findings on 23 children who were the victims of an accident previously reported (Abst. 3528, Vol. 23). The children were treated with a high concentrate of vitamin D in the belief that it was cod liver oil.

Vol. 24, No. 2

Three died. The intoxication varied in intensity according to age and the dose given; the signs and symptoms accompanying the different degrees of severity are tabulated.—E. M. Hume.

2384

KÖLBL, H. Serumchemismus bei der D-Hypervitaminose. [Serum chemistry in vitamin D excess.] *Öst. Ztschr. Kinderheilk.*, 1953, 9, 22-31. [Kinderklin., Univ. Vienna.]

The biochemical findings, including electrophoresis of the serum proteins, on 18 of the patients referred to in the preceding abstract are tabulated. They were obtained in the period after recovery had begun.—E. M. Hume.

2385

SWOBODA, W. Die Röntgenbefunde bei Vitamin-D-Überdosierung. [X-ray findings in vitamin overdosing.] *Öst. Ztschr. Kinderheilk.*, 1953, 9, 32-46. [Kinderklin., Univ. Vienna.]

The results are reported of X-ray examination of 13 of the same patients (see preceding Absts.). Calcification of the soft parts was confined to the dura mater and peri-articular regions.

E. M. Hume.

2386

BOLTZ, W. and WÖLKART, N. Über tödliche Vergiftungen durch Überdosierung von Fortedol (Calciferol). [Fatal intoxication by overdosing with Fortedol (calciferol).] *Öst. Ztschr. Kinderheilk.*, 1953, 9, 47-57. [Inst. Gerichtl. Med., Univ. Vienna.]

Of the 3 victims of the accident just described (see preceding Absts.) who died, one, 7 months old, succumbed to pneumonia 14 days after the first daily dose of 3 teaspoonsful of Fortedol (248,000 I.U. vitamin D per ml.). Only the liver and kidneys were available for examination. The kidneys showed severe pathological changes. The other 2 children were aged 20 months and 4 years. The bodies were exhumed, and decomposition was far advanced, but pathological changes in the kidneys and other signs made a retrospective diagnosis of vitamin D excess possible.

E. M. Hume.

2387

PATEISKY, K. Elektroencephalographische Untersuchungen bei Fortedol-(Vitamin D₂-) Überdosierung. [Electro-encephalographic investigation of overdosing with Fortedol (vitamin D₂).] *Öst. Ztschr. Kinderheilk.*, 1953, 9, 58-65. [Psychiat.-neurol. Klin., Univ. Vienna.]

It was possible to obtain an electro-encephalogram of only 3 of the victims of the vitamin D accident (see preceding Absts.). All were from one family. One had epileptic fits and 2 had attacks of cramp. Examination did not take

place until many months after the end of overdosing. The results for one child were within normal limits; for the other 2 they were profoundly abnormal. It is hoped in the future to examine more of the children.—E. M. Hume.

DENTAL DISEASES

2388

GABOVICH, R. D. and OVRUTSKII, G. D. O profilakticheskoi flyuorizatsii zubov. [**Preventive fluoridation of teeth.**] *Stomatologiya*, 1953, No. 2, 9-11. [Kaf. Obshch. Khim., Med. Stomatol. Inst., Leningrad.]

It has been shown experimentally by the application of 75 per cent. fluoride paste to the teeth of 7- to 14-year-old-children that it is sufficient to treat only one side of a tooth in order to protect against caries. This contradicts the theory that it is only that part of the tooth which comes into actual contact with the paste that benefits from the treatment. The modification used simplifies treatment and cuts down the time for rubbing on the paste by about half.—W. Hughes.

DEMOLE, V. Valeur diététique du fluor, son effet anticarie. [**Dietary value of fluorine; anti-caries effect.**] *Gegenwartprobleme der Ernährungsforschung, Symposium, Basle*, October 1952, 261-279 (with discussion 280-284). Verlag Birkhäuser, Basle, 1953. Price Swiss fr. 32. [Lausanne.]

2393

WILLIAMSON, M. M. **Endemic dental fluorosis in Kenya. A preliminary report.** *East African Med. J.*, 1953, **30**, 217-233.

A survey of the water supplies in Kenya showed a high fluoride content in many parts but especially in the south-western districts. Bore-hole, well and lake water had the highest F contents and the dust from the shores of Lake Nakuru contained 5600 p.p.m., of which 450 were soluble. The fluorides were derived mainly from weathered volcanic tuffs of tertiary origin. Examination of 4500 children and adults for dental fluorosis showed that all races were affected, but the incidence was highest in Asians and lowest in Europeans, 57.9 and 23.0 per cent., respectively, having mottled teeth. The need for further work is stressed. See Abst. 1148, Vol. 24.—L. Wills.

2394

NEVILL, L. B. and BRASS, W. **Preliminary report on dental fluorosis in Kenya European children.** *East African Med. J.*, 1953, **30**, 235-242. [Kenya Med. Dept.]

Examination of 1202 up-country European children aged from 7 to 14 years during 1952 showed that 30 per cent. had some degree of dental fluorosis and 40 per cent. had faulty teeth. The order of increasing incidence of dental defects closely paralleled that of decreasing incidence of fluorosis. The percentage of children with dental defects was 7 in those with mild fluorosis, 21.4 in those with moderate or severe fluorosis, and 50 in those with no sign of fluorosis. The highest incidence of fluorosis was in children drinking well or bore-hole water and the lowest in those drinking township or rain water; the incidence of dental defects was the reverse.—L. Wills.

2395

KAWAHARA, H. [Odontological observations on the fluorosis in Mt. Aso-volcano district. 2.] *Shikoku Acta Med.*, 1953, **4**, No. 1, 32-38. [Dept. Int. Med., Sch. Med., Univ. Tokushima.] In Japanese: English summary.

Drinking water from artesian wells in different villages in the district had F contents between 0.9 and 3.5 p.p.m. A positive relationship was found between the degree of mottling in the teeth of the children and the amount of F in the village water. Where the content was high signs of chronic fluorosis were present and there was a decline in the physique of the children. (From summary.)

HADJIMARKOS, D. M. **Dental caries among elementary school children in Oregon.** *J. Pediat.*, 1953, **43**, 393-397. [Dept. Foods Nutrit., Oregon State Coll., Corvallis.]

N.A. and R., April 1954

Earlier work in Oregon with children, 14 to 16 years of age, demonstrated their high degree of susceptibility to caries (Abst. 4043, Vol. 19). The present report concerns 1534 children aged from 5 to 12 years, the entire elementary school population of one town. Caries in deciduous teeth appeared in 78.0, 89.1, 88.7 and 88.7 per cent. of children at 5, 6, 7 and 8 years of age, respectively. In permanent teeth the incidence ranged from 34.4 per cent. at 6 to 98.6 per cent. at 12 years of age. The condition of first permanent molars was considered in particular, and these teeth were found to account for almost the entire DMF rate between 6 and 9 years and for half that at 12 years.

The findings show a higher incidence than has been reported from Maryland and Minnesota, and the need for further investigation of the cause is urged.—D. Harvey.

IMMUNITY

2399

DANCIS, J., OSBORN, J. J. and JULIA, J. F. **Studies of the immunology of the newborn infant. 5. Effect of dietary protein on antibody production.** *Pediatrics*, 1953, **12**, 395-399. [Dept. Paediat., Coll. Med., Univ. New York.] Spanish summary.

For part 3 see Abst. 3351, Vol. 23.

The manner of immunisation and the titration of antitoxin response are described by Osborn *et al.* (*Pediatrics*, 1952, **9**, 736). Two groups of 10 infants under 3 weeks of age received artificial milk mixtures with protein levels of 2.0 and 3.6 per cent., respectively, protein providing 10 and 20 per cent. of the energy value. The infants were immunised either during the first week of life, at 1 month, or at 3 to 4 months of age.

There was no apparent difference in antibody response to diphtheria toxoid between the 2 groups. It is suggested that a high level of milk protein does not measurably improve antibody production.

D. Duncan.

VEST, M. **Nahrungsmittelallergie, insbesondere Kuhmilchallergie bei Säuglingen. [Food allergy, especially cow's milk allergy in infants.]** *Ann. paediat.*, 1953, **181**, 277-294. [Kinderspital, Basle.] English and French summaries.

Full accounts are given of 9 infants with allergy to cow's milk and one with allergy to bananas. Leucocytosis was found, with a strong shift to the left, and later eosinophilia. The Prausnitz Küstner reaction was positive in only 2 cases. The result of investigations on antibody formation are reported separately in the next Abstract. In general the transition to soya feeding was easy and successful, except in one infant who was allergic to soya protein as well as to cow's milk and was given a diet of wheat germ, oats, vegetables and fruit, with Ossopan as a source of Ca. Until the allergy disappeared the child made excellent progress on this diet.

The introductory section of this paper, dealing with allergies, their diagnosis and treatment, contains 91 references.—M. B. Richards.

2401

BERGER, E. **Komplementbindende Antikörper gegen Nahrungsmittel bei Kindern. [Complement-fixing antibodies to foods in children.]** *Ann. paediat.*, 1953, **181**, 295-305. [Kinderspital, Basle.] English and French summaries.

By the complement fixation test it was shown that children can form antibodies against cow's milk, soya bean protein and oats. Positive results were obtained in 20 of the 84 children tested, a proportion smaller than that reported by other authors. Discrepancies are considered to be due primarily to differences in serological technique. The complement-fixing antibodies could be demonstrated in strong antigen concentrations, the "left" zone, and also in very dilute concentrations, the "right" or "eczema" zone. In several cases complement-fixing antibodies were present in children who showed no skin affection or other allergic sign. The term "eczema" zone should be used with reserve, since the manifestation of complement-fixing antibodies appears to depend on the serological technique, and the presence of antibodies in the "eczema" zone is not necessarily linked with the presence of eczematous conditions. Practical significance can be attached to the presence of complement-fixing antibodies only when other criteria support the diagnosis of an allergic disorder. Thus in one case of cow's milk allergy which was tested repeatedly at intervals of about 3 weeks, the disappearance of complement-fixing antibodies coincided with the point when tolerance of cow's milk was achieved.

Although the proof of antibodies has a limited diagnostic value, the results are of importance in nutritional physiology, in that they show that the proteins of cow's milk, soya bean and oats are not completely broken down in the gastro-intestinal tract, but are partially absorbed as such, and can lead to the formation of antibodies.

RATNER, B., UNTRACHT, S., MALONE, H. J. and RETSINA, M. **Allergenicity of modified and processed foodstuffs. 4. Orange: allergenicity of orange studied in man.** *J. Pediat.*, 1953, **43**, 421-428. [Dept. Paediat., New York Med. Coll.]

For previous parts, see *Ann. Allergy*, 1952, **10**, 675; 682; 690.

When a special brand of canned orange juice devoid of seed protein and peel oil, previously

investigated with guineapigs, was given by mouth to children who had been passively sensitised with serum from a patient highly sensitive to orange, no local reaction ensued, and the same was found when 2 oz. of the juice was given along with 1 ml. of a 1:100 dilution of orange seed protein. When another group of passively sensitised children were given 8 oz. of the same juice with 1 ml. orange peel oil, there was reddening and irritation about the mouth, and some had gastric discomfort, but none had local reactions. Six children sensitive to orange were able to take the special orange juice without any allergic reaction. From these experiments and injection tests it was concluded that orange seed protein does not readily traverse the gastro-intestinal wall, that orange peel oil is an irritant rather than an allergen, and that most cases of so-called allergy to orange arise from irritation by the peel oil.—W. M. Deans.

THERAPEUTIC AND PREVENTIVE DIETETICS

GASTRO-INTESTINAL CONDITIONS

2414

CHAUDHURI, K. C. **Bio-chemical changes in diarrhoea of children, their interpretation and application in therapy.** *Indian J. Pediat.*, 1953, 20, 193–207. [Calcutta.]

Values for haematocrit, plasma CO_2 -combining power, serum and urine chloride are tabulated for 19 infants aged from 4 to 42 months, suffering from acute diarrhoea. All were previously malnourished. Eight died. In these haematocrit was high, CO_2 -combining power was low and serum and urine Cl were within normal limits. In non-fatal cases haematocrit was low, CO_2 -combining power was high and Cl levels were normal. In a second and third series of children with chronic diarrhoea, age ranged from $1\frac{1}{2}$ to 16 years and nutritional condition was fairly good. Values are tabulated for serum K in the second series of 18 children and for serum K and Na in the third series of 10 children. In general these values were within normal limits.

Treatment is discussed. In cases where there is fluid loss the first consideration is to re-establish fluid balance by administering adequate quantities of the appropriate repair solutions and simultaneously attempting to provide adequate calories and protein.—F. C. Aitken.

THYROID DISEASE

2418

GREER, M. A. and ASTWOOD, E. B. **Treatment of simple goiter with thyroid.** *J. Clin. Endocrinol.*, 1953, 13, 1312–1331. [New England Centre Hosp., Boston, Mass.]

A historical review of the literature is given.

Fifty patients with non-toxic goitre were treated with thyroid in doses from $\frac{1}{2}$ to 6 grains, usually 2 or 3 gr., daily and were examined after intervals which varied from 1 week to 2 months. Forty comparable and untreated patients were also examined. Thyroid enlargement of 3 types, diffuse, multinodular or mononodular, was studied and patients were grouped into those in whom the enlargement disappeared, was reduced or showed no change. Of diffuse goitre 23 cases were treated and the numbers so classified were 10, 10 and 3; for 26 untreated cases the numbers were 4, 0 and 22. Of multinodular goitre 9 cases were treated and the corresponding numbers were 3, 3 and 3; for 6 untreated cases the numbers were 0, 1 and 5. Of mononodular goitre 18 cases were treated and the numbers were 7, 5 and 6; for 8 untreated cases the numbers were 1, 0 and 7. The response was more favourable in diffuse than in nodular goitre. Age was not of importance, nor was duration or extent of the enlargement, except that greatly enlarged glands tended not to regress completely.

It is stated that I therapy, though effective when the element is deficient or when a defect in the concentrating mechanism exists, may be ineffective when the defect is beyond that stage. Thyroid therapy, on the other hand, may reduce the size of the gland regardless of the nature of the defect. For that reason the infrequency of its use is surprising.—B. W. Simpson.

MORREALE DE CASTRO, G., ESCOBAR DEL REY, F., MORA LARA, J. R. and ORTIZ DE LANDÁZURI,

E. Bases científicas que aconsejan el empleo de la sal iodada en la profilaxis del bocio endémico. [**Scientific bases for the use of iodised salt in prophylaxis of endemic goitre.**] *Rev. clín. española*, 1953, **50**, 285-289. [Clín. Méd., Univ. Granada.] English, German and French summaries.

Estimations were made of I and Ca in waters from 33 districts of the province of Granada. The data indicated a close relation between the I content of the water and the intensity of endemic goitre. Where goitre was prevalent, the I content was distinctly low, less than 0.3 μg . per litre in about 2/3 of the samples, while in regions free from goitre the values were from 1.0 to 1.5 μg . It is concluded that there is no obvious relation between the Ca content of the water and the presence or absence of goitre. In the authors' view the low I content of the water is an index of a total deficit in the diet, and they recommend the initiation of a campaign for the use of salt iodised with 5 to 20 mg. KI per kg.—M. B. Richards.

2420

KAMCHATNOV, V. P. Sravnitel'naya kharakteristika soderzhaniya margantsa v pishchevykh produktakh v endemicheskikh i neendemicheskikh po zobu raionakh. [**Relative characteristics of the manganese content of food products in endemic and non-endemic goitre regions.**] *Gigiena Sanit.*, 1953, No. 2, 33-35. [Kaf. Obshch. Gig., Kazan. Med. Inst.]

Manganese was estimated in oats, wheat, tomatoes, carrots, peas, potatoes and cabbages grown in 3 areas, where goitre is strongly endemic, weakly endemic and not endemic. Experiments confirmed that there is probably a relation between the Mn content and the vitamin C activity of the vegetables grown in these areas. There is a relation between Mn content and the distribution of goitre. Experimental and other published data indicate that high Mn and Fe contents and low I and vitamin C contents are conditions which favour the development of endemic goitre.—W. Hughes.

ANAEMIA

2421

ADAMS, E. B. and WILMOT, A. J. **Megaloblastic anaemia of pregnancy and the puerperium.** *S. African Med. J.*, 1953, **27**, 1028-1032. [King Edward VIII Hosp., Durban.]

Severe typical megaloblastic anaemia occurred in 8 Indian and 6 African women in pregnancy or the puerperium. None of the women appeared malnourished, though all were poor and their diets were deficient in protein. Total serum protein was generally low and in 4 of 5 patients was below 5.5 g. per 100 ml.; after treatment it rose to

within normal limits, but if the albumin : globulin ratio was originally reversed, it remained so. No patient showed signs of involvement of the nervous system. Free acid was present in the gastric juice of 11 of 12 patients examined and serum bilirubin was normal except in 2 where it was slightly raised. One patient died of suppurative pyelonephritis, 9 patients were successfully treated with oral folic acid, 2 made good responses to parenteral vitamin B₁₂ and 2 to combined folic acid and vitamin B₁₂ therapy. In the discussion it is pointed out that no case of severe Fe deficiency in an African woman was seen during the year in which the megaloblastic patients were investigated and that in Indian women hypochromic anaemia appeared to be more common than megaloblastic anaemia during pregnancy and the puerperium.—L. Wills.

OTHER CONDITIONS

2422

DOXIADIS, S. A., GOLDFINCH, M. K. and HOLT, K. S. **Alkalosis in infants. Treatment by intravenous infusion of ammonium chloride.** *Lancet*, 1953, **265**, 801-804. [Dept. Child Health, Univ. Sheffield.]

Aqueous M/6 ammonium chloride was infused at rates of from 0.5 to 1.5 ml. per min. into the scalp veins of 5 infants with pyloric stenosis and alkalosis and 2 hydrocephalic infants with normal acid base balance. The average fall in plasma CO₂ level was 0.43 m.equiv. per litre per ml. ammonium chloride infused per kg. bodyweight.

Infusion of ammonium chloride was preceded by intravenous infusion of saline-glucose or glucose solution, which prevented the study of renal response to ammonium chloride, but the diuresis in the 2 control infants was significantly greater than in the infants with alkalosis.

Generalised convulsions occurred in 2 infants with pyloric stenosis, but these were attributed not to ammonium chloride administration but to water intoxication.—F. C. Aitken.

MARSON, F. G. W. **Studies in gout, with particular reference to the value of sodium salicylate in treatment.** *Quart. J. Med.*, 1953, **22**, 331-346. [Dept. Therap., Univ. Birmingham.]

In the course of a detailed study of the possibility of mitigating chronic gout by keeping the serum uric acid down by prolonged administration of sodium salicylate, experiments with 8 gouty men who received alternate low-purine (lacto-vegetarian) and high-purine diets, supplying about 0.2 and 0.5 g. purine N, for from 7 to 11 days, confirmed the belief that the purine intake affects the serum uric acid value, the respective mean values being 6.4 and 7.7 mg. per 100 ml. It is considered, however, that a purine-free diet is unlikely to alter materially the clinical course of gout.

For 100 non-gouty adults, healthy subjects or hospital patients on a normal mixed diet, the mean serum uric acid values in mg. per 100 ml. were 4.54 ± 0.15 , S.D. 1.08 and 3.82 ± 0.14 , S.D. 1.00 for men and women, respectively.—W. M. Deans.

Vol. 24, No. 2

[Blegdams Hosp., Copenhagen.] English summary.

Prolonged treatment of patients with cardiac decompensation with low-salt diet and mercurial diuretics leads to a characteristic state with thirst, anorexia, exhaustion, apathy, muscular weakness and giddiness. Renal function is reduced and blood urea rises. Blood Cl falls and finally also Na and K. NaCl is curative.

The etiology is discussed and the view is advanced that the mercurial drug stops tubular reabsorption of Cl, not of Na as is usually supposed. I. Leitch.

FERGUSON, M. H. and KAY, L. A. **Sodium concentration in drinking water and other fluids and its significance in restricted sodium intake.** *Canad. Med. Assoc. J.*, 1953, **69**, 491-493. [Dept. Physiol., Fac. Med., Univ. Manitoba.]

Water from 63 of 165 samples taken from sources of public supply in Manitoba contained more than 100 p.p.m. Na; 13 contained more than 500 p.p.m. Beverages such as Coca-Cola and beer reflected the Na concentration of the local water supply. Water-softening processes considerably increased the Na content of the water. While the Na content of water and beverages is unimportant for the average adult, a litre of water containing 100 p.p.m. would contain half the daily allowance for a patient on a low salt intake of 200 mg. Na.—D. Duncan.

Sixteen patients with moderate or advanced cirrhosis were given a diet providing 2500 Cal. and 1 g. protein per kg. bodyweight. An extensive series of investigations was made of clinical signs, blood composition, liver function and urine composition. Each patient was then given intravenously 200 ml. of 5 per cent. casein hydrolysate with 20 ml. of 2 per cent. methionine solution daily and after 4 weeks the examinations were repeated. The patients were classified in 2 groups of 8, in respect especially of diuresis and diminution of ascitic fluid, one with clinical improvement and the other with equivocal results. A detailed statistical analysis was made of the data.

From the data before treatment there was evidence that the groups differed mainly in respect of their metabolism of protein. After treatment it was found that the group which had improved clinically also showed improvement in liver function, but the other group showed no such improvement.—D. Harvey.

LEEVEY, C. M., ZINKE, M. R., WHITE, T. J. and GNASSI, A. M. Clinical observations on the fatty liver. *Arch. Int. Med.*, 1953, **92**, 527-541. [Dept. Med., Jersey City Med. Centre, N.Y.]

In 102 patients aged from 4 to 77 years in whom routine liver biopsy showed a fatty liver the proportion of fat in the section was from 10 to 30 per cent. in 30 patients, from 30 to 80 per cent. in 41 patients and over 80 per cent. in 31 patients. The most important cause was a diet poor in lipotropic factors, frequently associated with alcoholism. No correlation was shown between the degree or duration of the alcoholism and the severity of the steatosis. The presence of clinical disorders and abnormalities in liver function tests varied roughly with the degree of steatosis and improved when the fat was mobilised after treatment. There was no significant difference between the rate of mobilisation of the fat in patients receiving a high-protein diet and no other treatment and that in other patients receiving, as additions to the diet, vitamin preparations, choline,

methionine, vitamin B₁₂ or adrenal steroids, alone or in combination. Prolonged observations of 20 patients showed that in 9 who continued on a good diet with no alcohol there was no evidence of liver disease, but that of 11 patients who reverted to a poor diet with alcohol, 7 developed cirrhosis, 2 had mild fibrosis and 2 who had no fibrosis showed fatty infiltration. There was no significant change in the results of the liver function tests in those patients who developed cirrhosis.—L. Wills.

TOLSTRUP, K. On psychogenic obesity in children. 4. *Acta paediat.*, 1953, **42**, 289-304. [Gentofte, Denmark.] French, German and Spanish summaries.

This study is based on 26 girls and 14 boys with obesity and the same numbers of controls, all but one between 7 and 16 years of age, from Odense and its neighbourhood.

All but one of the fat children were or had been excessive eaters, especially of extra meals. Thirteen showed low bodily activity, but none of the controls did so. The local diet, rich in carbohydrate and fat, is itself likely to predispose to obesity. In 5 girls and 2 boys the excessive eating was definitely ascribed to psychological conditions, and in 4 girls and 2 boys these were thought to be probable the cause, but only 3 of the former group had the particular psychological background described by Bruch (for references and other Danish studies see Abst. 5116, Vol. 23).—W. M. Deans.

PENNINGTON, A. W. Obesity: overnutrition or disease of metabolism? *Amer. J. Digest. Dis.*, 1953, **20**, 268-274. [Med. Div., E.I. du Pont de Nemours and Co., Wilmington, Del.]

N.A. and R., April 1954

Published data of energy balance studies are quoted to show that on the average during restriction of energy intake there is a decline in basal energy expenditure in the obese, a greater decline in normal subjects and no decline in normal subjects who have first increased their weight by overeating. It is suggested that obesity is frequently due to some metabolic aberration involving the regulation of fat storage. Since restricted energy intake may have harmful effects, the dietary treatment of choice is a low-carbohydrate regimen with meat and fat to appetite.—F. C. Aitken.

2441

WILSON, D. **A study of spinal osteoporosis.** *Proc. Roy. Soc. Med.*, 1953, **46**, 977-981.

In this address the approach is clinical. The quality of the diet of the 36 subjects was judged by verbatim questioning. Many of the patients were women and the disorder was of menopausal origin; in these, endocrine treatment, if instituted before vertebral collapse, was valuable. Osteoporosis of nutritional origin was alleviated only slowly by Ca and vitamin D in the diet.

D. Harvey.

2443

BOINES, G. J. **Nutrition in poliomyelitis.** *J. Clin. Nutr.*, 1953, **1**, 355-363. [Dept. Biol. Sci., Univ. Delaware, Newark.] Spanish summary.

Much importance is attached to the giving of a high-protein, high-energy diet from the very beginning of hospital treatment. To a routine hospital diet supplying 85 g. protein and 2220 Cal. daily is added a supplement of fat emulsion 4 oz., protein powder 2 oz., eggs 2, maize syrup 1 oz., milk 1 qt., which increases protein intake to 172 g. and energy intake to 3817 Cal. daily.

Capsules containing hesperidin and vitamin C are given daily.

It is believed that attention to nutrition in the management of poliomyelitis has resulted in superior clinical results.—F. C. Aitken.

HARDISON, W. A. and REID, J. T. **Use of indicators in the measurement of the dry matter intake of grazing animals.** *J. Nutrition*, 1953, **51**, 35-52. [Cornell Univ., Ithaca, N.Y.]

The use of Cr_2O_3 as an indicator for estimating the dry matter intake of grazing animals was studied in a comparison between steers receiving similar herbage grazed and hand-fed. The excretion of Cr_2O_3 at different times throughout a 24-hr. period and the effect of sampling at these times on the recovery of Cr_2O_3 were estimated. The pattern of excretion varied considerably between animals grazing and those being hand-fed twice daily. An estimate of dry matter intake calculated from a "grab" sample was accurate only when the pattern of excretion was known. As a result of these experiments samples taken from grazing steers at 6 a.m. and 4 p.m. were bulked on a wet weight basis and the amounts recovered represented on the average 99.95 per cent. of the Cr_2O_3 ingested.—D. M. Walker.

2452

LANCASTER, R. J., COUP, M. R. and PERCIVAL, J. C. **Measurement of feed intake by grazing cattle and sheep. 3. Marker technique for investigating the faeces output of grazing cows.** *N.Z. J. Sci. Technol.* [A], 1953, **35**, 117-126. [Ruakura Animal Res. Stat., N.Z. Dept. Agric., Hamilton.]

For previous parts see Absts. 133, Vol. 21 ; 2679, Vol. 23.

Chromic oxide was administered twice daily in gelatine capsules to 3 cows during a 40-day grazing period. Total collections of faeces were made and the recovery of chromic oxide was compared with representative samples twice daily or "grab" samples twice daily. Mean concentrations of chromic oxide in the night representative samples were about 12 per cent. higher than in the day samples. Grab sample means were much more variable.

Faeces output by individual cows over 5-day periods was estimated from individual grab sample data with an error of about 10 per cent. From the representative samples the amounts recovered during the period were estimated to be 102, 100 and 102 per cent. of the ingested Cr_2O_3 for the 3 cows.—D. M. Walker.

2453

RICHARDS, C. R. and REID, J. T. **The digestibility and interrelationships of various carbohydrate fractions of pasture herbage and a resolution of the components of crude fiber and nitrogen-free extract.** *J. Dairy Sci.*, 1953, **36**, 1006-1015. [Dept. Animal Husb., Cornell Univ., Ithaca, N.Y.]

Pasture of timothy and mixed grass was analysed at 3 stages of growth and the digestibility of the constituents was estimated with 2 groups of 3 bullocks, one group being given cut forage from areas adjacent to those grazed at the same time by the other group. Collection bags were used to collect all the faeces.

The method of estimating the composition of the grazed herbage is not fully explained, but the analyses differed from those of the cut forage, the grazing bullocks selecting the more leafy parts of the plant.

Estimation of cellulose, hemicelluloses, starch, sugars, pectins and lignin in addition to normal proximate constituents reduced the undetermined fraction of the dry matter to only a few per cent.

High negative correlations were obtained between the digestible dry matter content of the herbage and the content of lignin, crude fibre and N-free extractives in the grass, also between the contents of crude fibre, N-free extractives, cellulose and hemicelluloses in the faeces and the digestible dry matter content of the herbage. A high positive correlation was found between the crude protein content of the faeces and the digestible dry matter content of the herbage.

A modification of the normal system of analysis for proximate nutrients is suggested, which eliminates the estimation of crude fibre, but includes that of lignin. The application of this modified analysis to the measurement of total digestible nutrients is explained.—D. M. Walker.

2454

DIJKSTRA, N. D. **De verteerbaarheid en voederwaarde van johannesbroodpittenkiemmeel. [The digestibility and feeding value of the ground germs of carob beans.]** *Landbouwk. Tijdschr.*, 1953, **65**, 191-194. [Rijkslandbouw-proefstat., Hoorn.]

Carob germ meal is a by-product of the preparation of mannogalactan for use in industry. The sample used had the following approximate percentage composition: dry matter 89.4, crude protein 45.1, true protein 42.6, crude fat 5.2, crude fibre 3.6, N-free extract 40.2, and ash 5.9. Digestibility was estimated in a test in which 500 g. carob germ meal was given with 600 g. hay to 3 wethers. The average coefficients were, in the above order: 86.4, 90.3, 91.2, 82.9, 85.2 and 91.1. Starch equivalent is computed with Kellner's V for soya bean meal, 96, to be 74.3. The meal is therefore a valuable feedingstuff.—I. Leitch.

2455

DRZAS, E. and SKULMOWSKI, J. **Oznaczanie współczynników strawności niektórych pasz, używanych do żywienia trzody chlewnej. [On the digestibility coefficients of some feeds used**

in feeding pigs.] *Rocz. Nauk rol.* [B], 1953, 66, No. 2, 83-104. [Inst. Zootech., Dział Żywienia Zwierząt.] Russian and English summaries.

Notwithstanding the great changes, due to selection and management, of the condition of livestock, old coefficients of digestibility are still used. They differ considerably from those found by the authors. They are no longer applicable, and should be revised. Some new figures for pigs are given, for use as a temporary measure until new tables are established. (From summary.)—T. D. Bell.

2456

SKULMOWSKI, J. and TYTRO, W. Współczynniki strawności niektórych pasz, używanych do żywienia drobiu. [Digestibility coefficients of certain poultry feeds.] *Rocz. Nauk rol.* [B], 1953, 66, No. 3, 21-42. [Inst. Zootech., Oddział Paszoznawstwa, Dział Żywienia Zwierząt.] Russian and English summaries.

Many of the digestibility coefficients at present in use are obsolete. Coefficients were estimated for wheat, barley, maize, oats, rye, soya bean, meat-and-bone meal, bloodmeal and a mash of crushed oats, wheat and maize, barley bran and meat-and-bone meal. The results are presented in a table with the figures given by other workers. (From summary.)—T. D. Bell.

2457

BIELIŃSKI, K., SZYFTER-ZIOŁECKA, A., BIELIŃSKA, K. and FILUS, J. Strawność siana z lucerny sprzątanej w różnych okresach rozwoju wegetacyjnego. [Digestibility of alfalfa straw harvested at different stages of growth.] *Rocz. Nauk rol.* [B], 1953, 66, No. 2, 69-82. [Inst. Zootech., Zakł. Doświadczalny, Kołuda Wielka.] Russian and English summaries.

Alfalfa was cut at the following stages of growth: pre-bud, early bud, bud, early flower, flowering and end of flowering. It was given, in the form of chaff, to wethers and digestibility coefficients were estimated by the "silicium" [silica?] method.

The digestibility coefficients of organic substances were inversely related to the fibre content and were affected also by differences in the experimental animals and by differences in the chemical composition of the straw. (From summary.)

P. C. Jowsey.

2458

BIELIŃSKI, K., BIELIŃSKA, K. and GWIZDAŁA, A. Zmiany wartości pokarmowej porostu koni-czynny czerwonej w zależności od momentu jej sprzętu. [Changes of feeding value of red clover as affected by the time of harvesting.] *Rocz. Nauk rol.* [B], 1953, 66, No. 2, 49-67. [Inst. Zootech., Zakł. Doświadczalny, Kołuda Wielka.] Russian and English summaries.

Vol. 24, No. 2

Analyses of samples of red clover were made every 3 days for 42 days. Kellner's digestibility coefficient was used to calculate the feeding value. There was an inverse relation between crude fibre and digestibilities. The highest yields of digestible protein and feeding value were obtained from 14 to 7 days before flowering. A table indicates the best time for cutting red clover for different classes of stock, and gives the yield per hectare of dry matter, digestible protein and feed units. (From summary.)—T. D. Bell.

2459

GREENWOOD, D. A., WILCOX, E. B., STEFFEN, H., HARRIS, L. E. and SHUP, L. Feed supplements—sugar. Influence on animal carcass of feeding sucrose. *J. Agric. Food Chem.*, 1953, 1, 1112-1115. [Utah Agric. Exp. Stat., Logan.]

Sucrose, from 1 to 3 lb. per head daily, was given to 100 Hereford steers, 2 to 3 years old, for 3 or 6 days, and to 97 heifers for 3 or 5 days, before slaughter. All received the same basal ration. During treatment daily gain in liveweight was increased in all groups compared with controls, and liver weights were also greater. Dressing percentage was increased in the steers treated for 3 days.

With pigs 64 were given 0, 1, 2 or 3 lb. sucrose in addition to the basal ration for 3 or 12 days before slaughter, and 40 the same for 5 or 6 days. As with cattle, sucrose feeding increased the rate of daily gain and weight of liver.

There was no difference between groups of cattle or of pigs in cooking quality of flesh or liver, as judged by organoleptic and shear tests, and sucrose had no effect on the carbohydrate content of liver or muscle.—T. D. Bell.

2460

DAMMERS, J. and DIJKSTRA, N. D. Voederproeven met gedroogde melasse. [Feeding trials with dried molasses.] *Landbouwk. Tijdschr.*, 1953, 65, 476-481. [Rijkslandbouwproefstat. Hoorn.] English summary.

The percentage composition of the dry molasses was: dry matter 99.78, crude protein 12.72, true protein 0.78, carbohydrate 74.91 and ash 12.37.

Tests with 3 wethers in which 600 g. dry molasses was given daily with 600 g. hay gave digestibility coefficients, in the above order, of 88.7, 65.3, negative, 95.0 and 94.0. The digestibility of the crude fibre of the hay was reduced. The starch equivalent is computed to be 58.7 for ruminants and 58.2 for pigs.

Three groups each of 12 pigs weighing about 30 kg. each were uniformly fed for 7 days. Then one group continued on a normal ration and two got 6 per cent. of dry molasses to 60 kg. weight, and

thereafter one group had 12 and the other continued at 6 per cent., the molasses replacing part of the cereals. Daily weight gains were 642, 621 and 615 g. during the first stage and 729, 705 and 676 g. during the second. The difference is not big enough to suggest that molasses depressed growth rate.—I. Leitch.

2461

STEPHEN, J. **The salvage and utilization of food waste for animal feeding. (a) Collection and processing.**

LIVINGSTONE, A. M. **(b) Distribution and utilization.** *J. Roy. Sanit. Inst.*, 1953, **73**, 675-681; 681-687 (with discussion 687-692). [Luton.]

1. Methods of collection, boiling, concentration and fortification with protein-rich wastes, and the future prospects for food waste in view of the decontrol of feedingstuffs and possible cessation of compulsory collection are discussed. The estimated amount of food waste in house refuse in England and Wales is 1,200,000 tons per annum, but it is doubtful whether more than a third of this is utilised for animal feeding at present.

2. The yearly output of waste food concentrate (33 per cent. dry matter, 5 per cent. protein) is about a quarter million tons, equivalent to about 8 per cent. of the rationed feedingstuffs for pigs and poultry in 1951-1952. For pigs 1 ton has a feeding value of about 1/3 ton of good pig food containing 60 per cent. barley meal. On this basis the price of food waste concentrate has roughly kept step with that of cereal feeds but at present is slightly less. Reference is made to a Ministry of Agriculture investigation in which good results were claimed for the use of from 2 to 10 lb., average about 7½ lb. daily, for pigs from 8 or 9 weeks to 26 weeks, with about 3½ lb. meal daily. The waste food concentrate was also good for winter egg production and the rearing and fattening of chickens. All stock were remarkably healthy; this is ascribed to the mineral and vitamin content.

Modification of local council procedure, better publicity and the setting up of a national association of waste processing authorities are suggested to meet the situation arising from decontrol of feedingstuffs. "Waste food concentrate is an excellent stock feed which, on its merits, should be able to compete on a price basis with any other pig or poultry feed on the market."—W. M. Deans.

2462

ROGERS, C. F. and BELL, D. S. **Acceptability of high-drymatter silages.** *Ohio Agric. Exp. Stat. Res. Circular* No. 20, June 1953, pp. 22. [Wooster, Ohio.]

For 4 years silage was made from much-wilted meadow crops. The silages had over 40, usually about 65 per cent., dry matter, and were satis-

factory in taste and smell. They were given to sheep to replace half the ration of standard silage normally given, and though the animals ate the standard silage, to which they were accustomed, first, they readily cleaned up the experimental silages. The dry matter intake was greatly increased, but this did not affect the consumption of hay. In comparison with standard high-legume silage the intake of carotenoids was unexpectedly high. The tests were of short duration and only the acceptability of the silages can be assessed from the results reported. Further investigation into their value for long-term feeding is necessary.—T. D. Bell.

2463

DIJKSTRA, N. D. Proefnemingen over het ensilieren van gras met aardappelvezels en gestoomde aardappelen. [**Experiments in ensiling grass with potato pulp and steamed potatoes.**] *Versl. Landbouwk. Onderzoek.*, 1952, No. 58-10, pp. 20. English summary.

Silage was made in three different ways. First alternate layers of grass, 22 per cent. dry matter (DM), and potato pulp, 18 per cent. DM, were laid down. The quality was poor, pH 4.76, with considerable amounts of acetic and butyric acids and ammonia N equivalent to 20 per cent. of total N. Loss of DM was small, 6 per cent., but of protein high, equivalent to 20 per cent. of total N and 37 per cent. of true protein.

In the second test the grass and potato pulp were mixed by machine: DM 17.1 and 16.8 per cent. The silage contained more acetic but less butyric acid and less ammonia than the first lot. Loss of carbohydrate was greater but of protein less. Digestibility of the grass used, by wethers, was high; that of the protein of the silage much less.

In the third trial the potatoes were steamed and mixed with the grass by machine: DM 13.5 and 21.7. The silage was excellent, pH 3.79, little acetic and no butyric acid; little ammonia and the digestibility of the protein much better. Losses of carbohydrate and protein were still high and that is attributed to the low DM content of the grass.—I. Leitch.

SOKOLOV, A. V., KOSTIN, A. A. and GOLOBOV, A. G. Skarmlivanie lozhadyam belkovykh gidroliznykh drozhzhei v kombikorme i ikh vliyanie na perevarimost', azotisty i mineral'ny obmen. [Feeding protein hydrolysed yeast in the ration to horses and its effect on digestion and nitrogen and mineral metabolism.] *Konevodstvo*, 1953, No. 6, 20-25.

Horses were given the following ration: hay 40, oats 35, wheat bran 15, hydrolysed yeast 3, molasses 6.5, chalk 0.25, salt 0.25 per cent.; the yeast was excluded from the ration of a control group. In 6 months the average weight of animals in the test group increased by 19.9 kg., in the control group by 17.7 kg. There was no ill effect on health. The average daily balance of N and minerals was positive at the start of the test and after 4 months. The nutritive value of 100 kg. of the ration with yeast represents 72.98 kg. feed units, without yeast 71.51 kg. Six months' storage had no ill effect on the test ration.—E. W. Birse.

Vol. 24, No. 2

Anglo-Arab stud of the Coudelaria Paulista.] *Bol. Indust. animal, São Paulo*, 1952, **13**, 63-77. [Div. Zootec. Nutrição Animal.] English summary.

The number of mares on any one ranch varied from 17 to 39. There were recorded in all 381 mare-years with a mean fertility of 60.6 per cent. In percentages, abortions were 6 and stillbirths 1.8, deaths before weaning 7.9 and foals weaned 44.9. Services per gestation of fertile mares averaged 6.41. Old mares, 15 years and over, had more abortions and more deaths before weaning. Average age at first delivery was 4.93 years.

I. Leitch.

2475

PACHECO JORDAO, L., XAVIER DE CAMARGO, M. and FURTADO GOUVEIA, P. Eficiência, na reprodução, do plantel P. S. Ingles da Coude-laria Paulista. [Breeding efficiency of the stud of purebred English horses of the Coudelaria Paulista.] *Bol. Indust. animal, São Paulo*, 1952, **13**, 47-62. [Div. Zootec. Nutrição Animal.] English summary.

The data cover 258 mare-years, 11 thoroughbred mares, 1 Arab, 1 Anglo-Arab, 2 Trakehnen and 1 Hackney. In percentages, abortions were 7.4 and stillbirths 5, deaths before weaning 21, and survivals to weaning, in terms of mares served, only

29-1. Fertility averaged 49.2 and varied from 30 to 76.2 per cent. in different years. Mares that became pregnant required on the average 4.7 services. Average age at first delivery was 4.71 years and some, the older, mares, 15 to 21 years, were responsible for most of the early deaths. The stallions were of low fertility also.

The pasture grazed was of *Chloris gayana*, *Penisetum clandestinum*, *Melinis minutiflora* and *Hyparrhenia rufa*. A concentrate ration of maize, oats and wheat was used with legume hay and a salt mixture of NaCl, Co, CuSO₄, Mg and I.

MAGRUDER, N. D., KNOTT, C. B. and WILLIAMS, P. S. Ammoniated feed. Ammoniated industrial by-products in dairy heifer rations. *J. Agric. Food Chem.*, 1953, 1, 944-946. [Pennsylvania Agric. Exp. Stat., State College.]

An ammoniated hemicellulose extract (wood sugar derivative) was given at a 10 per cent. level in a grain ration to a group of 4 non-pregnant Holstein heifers during a 90-day trial. The extract supplied about 20 per cent. of the daily N requirement. A similar grain ration supplemented with soya bean oil meal was given to a comparable group of heifers. The rations of both groups were adjusted to comply with Morrison's recommended feeding standards for growing dairy cattle. Body-weight gains and feed conversion efficiencies were similar in both groups.—J. N. Aitken.

KNOTT, C. B., ROSS, E. B. and STEIN, J. F. Further studies of aureomycin in feed for-

mulas for dairy calves. *J. Dairy Sci.*, 1953, 36, 1201-1204. [Dept. Dairy Husb., Pennsylvania Agric. Exp. Stat., State College.]

Three groups of 12 Holstein bull calves were given 2, 6 and 10 g. aureomycin per 100 lb. of milk replacement, which consisted of non-fat milk solids 50, dried whey 10, distiller's dried maize solubles 15, soluble blood flour 10, dextrose 7 and oat flour 5 lb. with vitamins A and D, and a control group had no aureomycin. Alfalfa hay and a calf starter were also given to all calves to appetite. The calves given aureomycin gained in weight and in height at withers more rapidly than those without aureomycin. There was no significant difference between the groups in feed utilisation. The incidence of scours was low in all groups. Aureomycin did not influence the condition of the faeces.—J. N. Aitken.

2482

ELLSWORTH, S. A., HUFFMAN, C. F., SMITH, C. K. and RALSTON, N. P. Effect of feeding antibiotics to dairy calves: 1. Aureomycin and bacitracin feed supplements. *Quart. Bull. Michigan Agric. Exp. Stat.*, 1953, 36, 60-66. [Dept. Dairy.]

Newborn Holstein, Brown Swiss, Guernsey and Jersey heifer calves were used. Aureomycin was given in milk at a level of 1 mg. per lb. bodyweight to a group of 8 calves, and a group of 4 calves received bacitracin at the same rate. A group of 9 calves was used as control. All calves received whole milk for about 2 months and reconstituted skimmed milk for an additional 2 to 3 months. Alfalfa hay and a grain mixture were also given. Antibiotic feeding was discontinued at 100 days of age.

During the experimental period the supplemented calves made higher bodyweight gains and utilised their feed more efficiently than the controls. The growth rates of control and treated groups were similar after the withdrawal of antibiotics.

N.A. and R., April 1954

Bacteriological studies of faeces showed no difference between control and treated groups.

J. N. Aitken.

GREEN, W. W. and BURIC, J. **Comparative performance of beef calves weaned at 90 and 180 days of age.** *J. Animal Sci.*, 1953, **12**, 561-572. [Dept. Animal Husb., Univ. Maryland.]

From 1949 to 1951, 62 purebred Aberdeen-Angus and Hereford calves of both sexes were weaned either at 90 or 180 days and were then fed individually until 370 days of age. All calves were weighed at birth, 90, and 180 days, and also at the end of each week for 4 weeks after weaning, and at the end of each 28-day feeding period until 370 days old. Heifers weaned at 90 days were lighter in weight on reaching 180 days than those weaned at the later date, but at one year of age they had made up the difference. The average rate of gain per 28-day feeding period was more uniform for the 90-day than for the 180-day weaned calves.—E. L. B. Haskew.

ESKEDAL, H. W. and NIELSEN, J. Forsøg med fedning af slagtekvæg. [Experiment on the fattening of cattle for the butcher.] *Forsøgs-lab. København Beretn.*, 1953, No. 269, pp. 80. English and German summaries.

Experiments are described on the fattening of cattle for the butcher, with a total of 102 cows, 33 bullocks and a few calves. In each experiment there were equal numbers of controls and experimental animals, of which 34 cows were given 100 g. and 17 were given 50 g. methyl thiouracil preparation for 32 to 35 days. Data are given for the rations used, for initial and final liveweights, weight at slaughter, cold carcass weight, weight of liver and all offal. In 7 of the 9 tests with cows, the fat and dry matter contents of back muscles, as samples of the carcass, were estimated and, in one test, the weight of bone in 2 carcasses was ascertained.

Of the excess of liveweight at slaughter, about 47 kg. in cows given 100 g. of the drug, roughly 35 per cent. (16 kg.) was due to excess weight of stomachs and their contents. The treated animals looked fatter and the bullocks fetched a higher

price per kg. The analyses showed that the fat of meat was reduced by 100 g. of the drug daily, but not by 50 g. In all except 1 of these tests in which analyses were made, fat-free dry matter was also less in the treated animals; it was less in treated calves, but fat was higher.

[From these analytical data it has been computed that the mean difference in weight of carcass meat between 30 untreated and 30 comparable cows given 100 g. methyl thiouracil daily can be attributed to water and of the mean difference between 17 controls and 17 given 50 g. of the drug three-quarters was water.]-I. Leitch.

2486

KLOSTERMAN, E. W., KUNKLE, L. E., BENTLEY, O. G. and BURROUGHS, W. **Supplements to poor quality hay for fattening cattle.** *Ohio Agric. Exp. Stat. Res. Bull.* No. 732, May 1953, pp. 20. [Wooster, Ohio.]

Between 1948 and 1952 trials were made in fattening Hereford steers on poor quality hay with different protein supplements. Full details of the treatments and performances of the groups of about 10 steers each are given in tables.

All animals received hay, corn-and-cob meal and minerals, and a supplement. This was usually soya bean meal with either partial or complete replacement by meat scraps, alfalfa meal, urea, dried distiller's solubles, molasses or maize silage.

A mixture of meat scraps and soya bean meal was no better than soya bean meal alone, nor were mixtures of soya bean meal with urea, meat scraps and distiller's dried solubles in different proportions. Alfalfa meal was better than soya bean meal when completely replacing it, but cost slightly more. Urea was satisfactory as a source of N when given as 50 per cent. of the protein supplement. The addition of molasses, or the ash of alfalfa or molasses fermentation solubles, or a complex trace mineral mixture, improved the poor quality hay ration, which suggested a deficiency of trace elements in hay. Molasses also improved performance on good quality hay rations, in that 0.75 lb. soya bean meal was as good as 1.5 lb. when molasses was given. Maize silage improved rates of gain on poor quality hay but not on good quality hay. The difference between good and poor quality hay was highly significant, and indicated the importance of producing the former for economical fattening.

2487

MILLER, J. I. and MORRISON, F. B. **Use of pasture for fattening steers.** *Cornell Univ. Agric. Exp. Stat. Bull.* No. 890, March 1953, pp. 35.

A series of 9 trials was made between 1943 and 1949 comparing different methods of feeding steer calves and yearlings on pasture with or without

supplements. Full experimental results are presented in detail.

Calves purchased in autumn, wintered on a growing ration, put to pasture till August and full-fed in dry lot before slaughter as yearlings ate less maize but more hay and silage and were more profitable than similar calves raised in dry lot throughout. Heavy calves receiving a wintering ration plus 2 lb. maize gained faster than those not receiving the maize, but when they were turned out to pasture the latter gained more quickly. Over the whole period, which included finishing in dry lot, those receiving maize in the first period had a greater rate of liveweight increase.

Yearling steers purchased in spring and fattened off grass gave the poorest return of the feeding methods studied. Full feeding with ground maize on pasture increased rate of gain and profit. Steers fed in this way were also slightly more profitable than similar beasts that grazed till August and were finished by full feeding in dry lot. When the period of grazing was extended the financial returns were slightly better.

On the whole it was more profitable to purchase calves in the autumn, feed through the winter, and fatten on pasture with a supplement than to purchase in the spring for fattening. The winter feeding should be mainly of good roughages.

2488

HOLMES, W. **Feeding grass. The use of grazing silage, hay and dried grass in feeding dairy and beef cattle.** Dept. Agric. Scotland Advisory Leaflet No. 25 (New Ser.), H.M.S.O., Edinburgh, 1953, pp. 20. Price 1s. net.

General principles are outlined for the most effective and economical use of grassland by cattle. Rations using silage, hay and dried grass are suggested for different classes of stock. The compositions of the different grades of preserved grass are given, with advice on how to classify them in practice. The changes in the value of grass with stage of development, soil fertility, rate of growth and pasture management are discussed.—T. D. Bell.

2489

DODSWORTH, T. L. **Grass silage for beef.** *Scot. Agric.*, 1953, **33**, 88–91. [N. Scotland Coll. Agric.]

Cross Shorthorn and cross Aberdeen-Angus steers were divided into 4 comparable groups of 6 animals each. The following rations were given: swedes, oat straw, hay and crushed oats; swedes and oat straw in the morning and silage in the evening; silage in the morning and swedes and oat straw in the evening; silage only. All animals were slaughtered and graded at the end of the trial. The group fed on silage alone graded better than the other groups, and the group fed

on silage in the morning and swedes and oat straw in the evening made smaller daily gains and showed the poorest degree of finish. There was little difference between the other two.—J. N. Aitken.

2490

VAN ARSDALL, W. J., HOEFER, J. A., BRANAMAN, G. A. and LUECKE, R. W. **Supplementing corn silage for fattening steers.** *Quart. Bull. Michigan Agric. Exp. Stat.*, 1953, **36**, 46–49. [Dept. Animal Husb.]

Steers of initial liveweight about 760 lb. were given maize silage to appetite and supplements of soya bean meal and molasses feed, soya bean meal, ground maize and soya bean meal, or ground maize and urea. They received 3.5 lb. of the supplement daily (3.82 of the maize and urea). They were fattened for 146 days to a liveweight of about 1100 lb. Daily liveweight increases were 2.33, 2.18, 2.07 and 2.37 lb. for the 4 groups, respectively. The grading at slaughter was nearly the same for all groups. The maize-urea group required least silage, and the soya-molasses group least supplement, per unit of liveweight gain.

2491

JOHNSON, L. E., MOXON, A. L. and SMITH, R. L. **Wintering beef cows on South Dakota ranges.** *S. Dakota Agric. Exp. Stat. Bull.* No. 419, May 1952, pp. 26.

The results of 4 wintering trials made between 1942 and 1950 at 2 centres in South Dakota showed that supplementary feeding was necessary for breeding cows maintained on the range. Stacked or windrowed hay, sorghum fodder or protein concentrate was used as a supplement, and a mineral mixture was given at all times. Ten lb. of good quality roughage was better than 1 lb. of 40 per cent. protein concentrate, but poor quality roughage was inferior. Twice or three times as much windrowed hay was needed as stacked hay. Over a period of years, the effect of inadequate rations on bodyweight of the cows was cumulative, and this was reflected in the calf crop and weight at weaning, but after one year only on the inadequate ration there was rapid recovery, and performance was not much below that of supplemented animals. The cows in these experiments were served between July and September and the calves were weaned in early November.

2492

BOTHA, J. P. **Further results of a spring resting period on the sour veld.** *Farming in S. Africa*, 1953, **28**, 335–339. [Agric. Res. Inst., Pretoria.]

Better liveweight increases were made by bullocks on sour veld burned in August (early spring) and grazed as soon as there was sufficient

growth than by those on paddocks rested on the average for 19 days after burning. The observations were made on 2 paddocks for 13 years. Over this period the rested paddocks maintained their productivity, but the unrested declined. It is suggested that a year without grazing every fifth year would maintain the unrested paddocks at a suitable level.—T. D. Bell.

2493

BARNARD, W. G. **The cattle of the Swazi.** Vet. Dept., Swaziland, Mpisi Series No. 4, May 1953, pp. 17.

This is a progress report of the work of the Mpisi Cattle Breeding Experimental Station. Purebred Afrikaner and Nguni herds and crosses between these breeds are maintained. Improvement of the Nguni is aimed at and selected bulls are reared for acquisition by the native farmers, but so far the response has been disappointing. Some experimental work on veld improvement is also in hand.—T. D. Bell.

BONSMAN, J. C., VAN MARLE, J. and HOFMEYER, J. H. **Climatological research on animal husbandry and its significance in the development of beef-cattle production in Colonial territories.** *Empire J. Exp. Agric.*, 1953, **21**, 154-175. [Dept. Animal Husb. Res., Mara Res. Stat., South Africa.]

From work done at the Mara and Messina Research Stations, and from observations made in the different climatic regions, the records of different types of cattle of exotic and indigenous breeds and their crosses were studied under semi-arid and sub-tropical environments in relation to heat tolerance, growth rate, fertility, resistance to disease and mortality rate. Lack of adaptability of a breed or strain to a particular environment results in slow growth, low fertility and high mortality. Although the mortality rate of crossbred and Hereford cattle has been reduced by selective breeding for increased adaptability, these cattle are still not so robust and resistant as indigenous stock. Six fundamental rules are recommended for the selection of cattle for these semi-arid and sub-tropical regions, and a variety of suitable breeds and types are suggested for 5 types of environment.—E. L. B. Haskew.

Vol. 24, No. 2

ments of milk cows according to present knowledge in the field of animal nutrition.] *Riv. Zootec.*, 1953, **26**, 277-281.

A review based on the U.S. National Research Council's recommendations.

2496

HANCOCK, J. **Studies in monozygotic cattle twins.**

7. The relative importance of inheritance and environment in the production of dairy cattle.
8. Performance of identical twins when uniformly treated after having been subjected to different treatments in the previous lactation.
9. The value of identical twins in short-term trials. *N.Z. J. Sci. Technol.* [4], 1953, **35**, 67-92; 93-96; 97-116. [Ruakura Animal Res. Stat., N.Z. Dept. Agric., Hamilton.]

7. The effects of 3 widely different levels of nutrition on milk, butterfat and casein production were estimated with 15 sets of monozygotic twins. The twins were divided into 3 groups of 10 animals each and were assigned to the treatments A, B and C so that 5 sets were split between treatments A and B, 5 between B and C and 5 between A and C.

Cows on the A treatment rotationally grazed a 10-acre pasture. Silage or hay was given whenever the grass was thought to be insufficient for their needs. All cows in this group received 1 lb. of a concentrate mixture for each 5 lb. of milk produced, irrespective of stage of lactation or level of production. Cows on the B treatment were allowed to graze a similar area of 10 acres and were treated in the same way except that concentrates were not given. Cows on the C treatment rotationally grazed an area of only 6 acres and received only 60 per cent. of the amount of silage and hay consumed by cows on the B treatment. Concentrates were not given. Milk weights were recorded daily and representative samples were analysed for butterfat and casein. Crude production figures were converted to a maturity equivalent basis by the addition of 70 and 35 lb. butterfat to the yields of 2- and 3-year-old heifers, respectively.

The experiment was continued over 3 consecutive milking seasons. Milk, butterfat and casein production of the animals on treatment C were reduced by about 30 per cent. below that on treatment A and by 10 per cent. below that on treatment B. Milk composition was only slightly affected by treatment.

Coefficients of heritability, defined as the proportion of the total variance directly due to genetic differences between individuals in a specified population, were determined for the characteristics studied, with the following results: milk yield 0.90, butterfat yield 0.86, casein yield 0.88, butterfat percentage 0.95 and casein percentage 0.94. Genetic correlations between the characteristics were also determined. The results are discussed in detail

and their importance in any programme of breeding and selection is emphasised.

8. The post-treatment performance of 10 of the original 15 sets of twins is reported. All animals were treated uniformly during the dry period following the termination of the above experiment.

Differences in bodyweight between poorly fed and well fed twins tended to disappear during the dry period when all sets were fed in the same way. Previous treatment had little effect on yield of milk, butterfat or butterfat percentage over a 200-day lactation.

It is concluded that, since the after-effects of previous treatments were negligible, identical twins can still be used for further trials involving milk and butterfat production provided the poorly fed members of the twin sets are given a chance to recover during the dry period preceding the new trial.

9. Two trials are described. In the first the effect of "steaming up" for 1 month before calving was estimated on 8 sets of twins. One member of each twin set received a concentrate mixture of crushed barley and linseed cake in the proportion of 4 to 1 at the rate of 1 per cent. of bodyweight daily. The remaining member of each set received no concentrate. After calving both groups were given concentrates at the rate of 1 lb. per 5 lb. milk produced for the first month and half this amount for the second. All animals had access to an autumn-saved pasture and received silage to appetite.

The meal-fed cows made greater weight gains and their calves were in general heavier than those of the controls. Treatment had no effect on bodyweights during the first 3 months after calving. During the same period milk and butterfat production increased by 10 and 11 per cent., respectively. Since bodyweight after calving was unaffected by treatment it was concluded that the higher production was not due to reserves on which the meal-fed animals could draw.

In the second trial turnips were compared with grass silage as a pasture supplement for milking cows. Nine sets of twins were split between the 2 treatments. A 17-acre pasture area was divided into 2 equal parts and one half was allotted to the silage group and the other to the turnip group. Both silage and turnips were given so as to supply about half the normal dry matter intake. This was done by giving the silage group 550 to 600 lb. and the turnip group 1000 lb. daily. The experiment was made over a period of 8 weeks, during the declining phase of lactation in midsummer when grass was scarce owing to drought. The turnip group lost weight rapidly during the first 4 weeks of treatment, but weight was rapidly regained on conclusion of the experiment.

The turnip-fed cows produced about 9 per cent.

more milk and butterfat than their pair mates on silage.

The value of identical twins in this type of short-term experiment is discussed briefly.—J. N. Aitken.

For details of management and housing see Absts. 4175, Vol. 19; 4420, Vol. 20; 2832 and 5049, Vol. 21.

Lactating Holstein, Jersey and Brown Swiss cows as well as 2 dry Jersey and 2 dry Brahman cows were used. During the winter of 1950 the studies were concerned with the effect of humidity at 12° and 40° F. and in the summer of 1951 at 75°, 85°, 95° and 100° F. Changing humidity did not affect the physiological reaction at low temperatures but above about 75° F. increasing humidity depressed the milk production and feed consumption of all animals. Feed consumption rapidly returned to normal during control periods at 65° F., and milk production returned to near its original level. The shape of the feed consumption curves with increasing temperature of the non-lactating Jersey and Brahman cows was similar to that for the lactating cows. The percentage of butterfat tended to increase with decreasing milk production but the percentage of solids-not-fat showed little, if any, change.

AITKEN, J. N., BOYNE, A. W. and CRICHTON, J. A. **The effect of feeding iodinated casein and L-thyroxine upon the health, reproduction and yield of a dual-purpose breed of cattle and a purely dairy breed.** *J. Dairy Res.*, 1953, **20**, 291-300. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Iodinated casein or L-thyroxine of equivalent potency was given to Red Poll (dual purpose) and Ayrshire (dairy) cattle for periods of 15 weeks during 4 lactations. The dose was 20 g. iodinated casein or 8 mg. L-thyroxine daily, reduced to 10 g. and finally 5 g. during the last 3 weeks of treat-

N.A. and R., April 1954

ment. The effects on general health, reproduction, bodyweight, milk yield and butterfat were recorded.

There was no adverse effect on general health or reproduction, though bodyweight declined temporarily in some of the treated animals; all the control animals gained weight. The long intervals between consecutive treatments allowed complete recovery. In the early stages of treatment there was an increase in daily milk yield, but this did not persist till the end of treatment. Control animals had significantly longer lactations than treated, and total lactation yield was not improved by treatment. There was no change in butterfat percentage.—T. D. Bell.

2500

ESKEDAL, H. W. Fedtfattigt og fedrigere kraftfoder til malkekøer. [**Low-fat and high-fat concentrates for milk cows.**] *Forsøgslab. København Beretn.*, 1953, No. 268, pp. 45. English and German summaries.

There were 4 experiments. In the first, 3 groups of cows were given pressed linseed cake, extracted linseed meal or linseed. Average daily data were: roughage consumed, 7.58; 7.43 and 6.83 feed units, intake of crude digestible fat 229, 112 and 580 g. and yield of fat-corrected milk 15.99, 14.60 and 16.97 kg. In the second experiment there were also 3 groups, with no oil, 117 g. rape oil or 91 g. soya bean oil daily per cow. Corresponding data were roughage 8.21, 8.20 and 8.20 feed units, fat intake 194, 321 and 294 g. and milk yield 13.91, 15.28 and 16.00 kg. There were only 2 groups in the third experiment, one with no oil and the other with an addition of 192 g. crude fat, mostly lard, and the data were: roughage 7.40 and 7.40 feed units, fat intake 100 and 292 g., and milk yield 15.33 and 17.15 kg. In the fourth experiment all 3 groups of cows had the same amounts of roughage, 8.21 feed units, but differences in the composition of the concentrate mixture gave intakes of 192, 254 and 252 g. digestible crude fat. In this case yields were 13.96, 14.41 and 14.48 kg., respectively. In all 4 experiments iodine values of the milk fat were estimated.

The results of all experiments indicated that milk yield was highest in cows getting the extra fat. The effect on the quality of the butterfat was generally to raise its iodine value and to overcome the hardness which is a character common in Danish butter produced during winter months. (From summary.)—D. Harvey.

PRATT, A. D. and MONROE, C. F. **Expeller vs. solvent process linseed oil meal for milking cows.** *Ohio Agric. Exp. Stat. Res. Bull.* No. 731, April 1953, pp. 18. [Wooster, Ohio.]

Vol. 24, No. 2

Expeller-process and solvent-extracted linseed oil meals were given to 2 groups of 13 milking Holstein cows during a 100-day trial. Both groups received the same basal ration. The expeller-process meal and the solvent-extracted meal contained 4.43 and 1.34 per cent. fat, respectively. In a second similar trial with 2 groups of 25 cows each the solvent-extracted meal used contained only 0.84 per cent. fat. In both trials roughage was given to appetite.

Statistical analysis of the results showed that there was no difference between the groups in the amount of fat-corrected milk produced. All animals gained weight during the trials.

The almost complete removal of the fat did not reduce the conditioning effect for which linseed oil meal is noted.—J. N. Aitken.

2502

LOOSLI, J. K. and WARNER, R. G. **Distillers feeds as protein supplements in concentrate mixtures for milking cows.** *J. Dairy Sci.*, 1953, **36**, 1135–1139. [Dept. Animal Husb., Cornell Univ., Ithaca, N.Y.]

The value for milk production of maize distiller's dried grains with solubles, maize distiller's dried grains and maize distiller's dried solubles was compared in rations in which they supplied the principal protein supplement to oats and barley. The 3 rations were adjusted to contain about 18 per cent. total protein. Holstein cows were used. Maize distiller's dried grains had a slightly higher value for milk production than the other two feeds. The differences were not statistically significant.

2503

PORTER, G. H., JOHNSON, R. E., EATON, H. D., ELLIOTT, F. I. and MOORE, L. A. **Relative value for milk production of field-cured and field-baled, artificially dried-chopped, artificially dried-ground and artificially dried-pelleted alfalfa when fed as the sole source of roughage to dairy cattle.** *J. Dairy Sci.*, 1953, **36**, 1140–1149. [Dept. Animal Indust., Storrs Agric. Exp. Stat., Univ. Connecticut, Storrs.]

Two experiments are described. In the first, milk production of cows given artificially dried, pelleted alfalfa hay was increased and butterfat decreased when compared with the other hays studied. In the second experiment consumption of hay in the pelleted form was reduced, with a consequent decrease in milk production. This result was attributed to the hardness of the pellets.

CASTLE, M. E. **Grassland production and its measurement using the dairy cow.** *J. Brit. Grassland Soc.*, 1953, **8**, 195-211. [Nat. Inst. Res. Dairying, Univ. Reading.]

For 3 years pastures of cocksfoot and white clover and ryegrass and white clover were grazed by groups of 10 cows, adjusted periodically so that the average stage of lactation of the groups was the same at all times. In 1949 the leys were rotationally grazed, and in 1950 and 1951 strip grazing with fore-and-aft electric fencing was practised. Silage was made each year and fed on the pasture during the grazing season, which was continuous from April to November. Total milk yield and quality of milk were recorded. Samples of the swards before entry of the cattle, from cages, and after grazing were analysed.

The ryegrass pasture gave 18.7 per cent. more milk per acre than the cocksfoot, though there was little difference between them in total dry matter per acre. The average dry matter consumption daily, calculated from the liveweight and liveweight changes of animals, was 2.9, 2.9 and 2.5 lb. per cwt. liveweight for 1949, 1950 and 1951, respectively. The average daily milk production for the 3 years was 25.1 lb. Butterfat and solids-not-fat percentages were at all times satisfactory. Estimated from the nutrient requirements of the stock, the total output of the pastures was 25.1 cwt. utilised starch equivalent per acre per year, but calculated from herbage data it was 9 to 23 per cent. more.

The use of the technique and its practical application are discussed.—T. D. Bell.

2506

GRIFFITHS, T. W. and FEATHERSTONE, J. **Making better use of silage.** *Agriculture, J. Minist. Agric. Engl.*, 1953, **60**, 409-411. [Nat. Agric. Advisory Serv., W. Midland Province.]

Well-made silage can be put to good use for fattening cattle or for milk production. The desirability of analysing the silage so that it can be properly rationed is emphasised.

In the feeding trial 4 Dairy Shorthorn steers, from 9 to 11 months old, gained on the average 1.37 lb. daily for 4½ months. The daily ration was 30 lb. silage and 4 lb. concentrate (oats 75, calf nuts 25 per cent.) for the first month; 30 lb. silage and 3 lb. oats (reduced to 1½ lb.) for the second month; and 40 lb. silage thereafter. They had oat straw to appetite all the time. The silage had 24.8 per cent. dry matter with 14.2 per cent. crude protein.

There were 15 Ayrshire cows in the milk production trial. They were given 60 lb. silage, 5 lb. hay and 7 lb. of a mixture of oats 90 and fishmeal 10 per cent. for maintenance and the first 2 gal.;

4 lb. of a mixture of oats 77, fishmeal 10 and groundnut cake 13 per cent. for the third gal.; and 3½ lb. dairy cake for each gal. over 3. The silage had 18.5 per cent. dry matter with 12.8 per cent. crude protein. Milk yield was well maintained, but dropped when the silage was reduced.

T. D. Bell.

2507

TURNER, C. **Self-feeding of silage.** *Agriculture, J. Minist. Agric. Engl.*, 1953, **60**, 358-362. [County Agric. Advisory Office, Buckinghamshire.]

A farm trial is reported in which winter handling of silage was avoided by allowing the dairy herd permanent access to a stack of silage in a concrete yard. The cows ate on the average 86 lb. per head daily, there was no waste and results to date seem encouraging. Further observations will enable improvements to be made in the system.

SINGH, H. and DAVE, C. N. **Investigations into the variations of quantity and quality of milk from different quarters of udder.** *Indian J. Dairy Sci.*, 1953, **6**, 97-103. [Minist. Food and Agric., New Delhi.]

Five Sindhi cows were hand-milked daily at the same hour by the same milker. Separate records were kept for the separate quarters, for the 2 fore and 2 hind quarters, and for the 2 right and 2 left quarters of each udder. The order of milking the quarters or pairs of quarters was varied. The results are presented in detail.

The 2 hind quarters yielded on the average 33 per cent. more milk than the 2 fore quarters, irrespective of the order of milking. The 2 right quarters yielded on the average 12.2 per cent. more milk than the 2 left quarters, irrespective of the order of milking.

It was concluded that the right hind quarter generally gave the highest individual yield.

PROCTER, J. and HOOD, A. E. M. **The close-folding of dairy cows.** 2. *J. Brit. Grassland Soc.*, 1953, **8**, 239-244. [Imperial Chemical Industries, Ltd., Jealott's Hill Res. Stat., Bracknell, Berks.]

Close-folding with about 70 cows per acre was compared with rotational grazing with about 10 cows per acre. The trial was made on 6 pairs of 3-acre paddocks, 3 pairs of which were of a second year cocksfoot and clover sward, while the other 3 consisted of first year timothy, meadow fescue, cocksfoot and clover. Pre-grazing and residue samples of grass were taken before and after each grazing.

The milk yields of the cows on the close-folding system were significantly higher than those on the

N.A. and R., April 1954

rotational system. Close-folding resulted in a 25 per cent. better utilisation of the herbage. These results are substantially in agreement with those already reported in Abst. 6042, Vol. 20.

REPRODUCTION

2514

FLIPSE, R. J., SNYDER, J. W., THACKER, D. L. and ALMQUIST, J. O. **Effect of total digestible nutrient intake on growth and reproductive development of dairy bulls.** *Pennsylvania Agric. Exp. Stat. Progr. Rep.* No. 104, May 1953, pp. 14. [State Coll., Pa.]

The rations of 4 groups of Holstein bulls were maintained during the first 2 years of life at 70,

100, 115 and 130 per cent. of the recommended allowances for total digestible nutrients. Records of sexual development, blood composition, growth and feed utilisation and semen quality were kept throughout the experimental period.

The age at which the first viable spermatozoa were obtained was delayed by 12 to 14 weeks in the group receiving only 70 per cent. of the recommended allowances when compared with the other groups. The semen obtained from the poorly fed animals was also of poorer quality.

Blood composition was not significantly affected by differences in intake of total digestible nutrients.

At 2 years of age bodyweights and heart girth measurements of the poorly fed group were significantly less and height of withers slightly less than those of the other groups. During the first 26 weeks the poorly fed animals utilised their feed less efficiently, but on the average over the 2-year period this group was most efficient.

JOHNSTON, J. E. and BRANTON, C. **Effects of seasonal climatic changes on certain physiological reactions, semen production and fertility of dairy bulls.** *J. Dairy Sci.*, 1953, **36**, 934-942. [Dairy Dept., Louisiana State Univ., Baton Rouge.]

This investigation was made over a 53-week period in a sub-tropical environment with 14 dairy bulls of the Holstein, Jersey and Guernsey breeds. The physiological reactions studied were pulse rate, body temperature and respiration rate. Semen samples were collected and evaluated for quantity and quality. Fertility was estimated on the basis of percentage of 60 to 90 day non-returns to first services. Statistical analysis of results showed that differences in fertility or body temperature between breeds were not significant. There was a significant breed difference in pulse rate throughout maximum temperature intervals of 40° to 60°, 60° to 70°, 70° to 80°, 80° to 85°, 85° to 90° and 90° to 95° F. There was a significant correlation between fertility and minimum and maximum temperature and vapour pressure when 6-week moving averages of these measurements were taken.—J. N. Aitken.

2516

JOHNSON, L. E., ALBEE, L. R., SMITH, R. O. and MOXON, A. L. **Cows, calves, and grass. Effects of grazing intensities on beef cow and calf production and on mixed prairie vegetation on Western South Dakota ranges.** *S. Dakota Agric. Exp. Stat. Bull.* No. 412, June 1951, pp. 39.

Studies were made of the effect of heavy, medium and light grazing of range pasture on the state of

the pasture and on the cattle. The observations were continuous from 1942 to 1950. During the first 5 years stocking was, for heavy, light and medium rates, 1.4, 2.3 and 3.1 acres per cow per month, respectively. In the following 4 years rates were intensified to 1.4, 2.1 and 2.8. Grazing was for 7 months annually, all animals receiving the same treatment during the winter.

The heavier the grazing, the less the weight gain during the grazing period. In some years there was a loss in the heavy grazing group. Through the years the differences between groups increased progressively, since the same animals were kept in these groups throughout the experiment. There was no difference in

calf crops between groups, but weaning weights followed the same trends as the liveweights of the cows.

The yield of foliage increased in the lightly grazed areas, was maintained in the moderate and declined in the heavy. For lightly, moderately and heavily grazed, the percentages of foliage removed were 37, 46 and 63, respectively. Though heavy grazing produced the best cow and calf gains per acre, when set against the deterioration of the pasture the result was not considered advantageous, and the general recommendation is: "Graze half and leave half". The suggested rate of grazing is 2.25 acres per cow per month.—T. D. Bell.

SHEEP

2517

JORDAN, R. M., BURKITT, W. H. and WILSON, J. W. **Sorghum as a feed for lambs.** *S. Dakota Agric. Exp. Stat. Bull.* No. 417, February 1952, pp. 11.

Grain from grain-type sorghum (Norghum) had the following percentage composition: dry matter 91.17, crude protein 12.15, ether extract 2.79, crude fibre 1.78, N-free extract 72.97, and compared favourably with maize. Grain from sweet sorghum had less N-free extract and more fibre.

In 3 trials with comparable groups of lambs, average daily gains were with maize 0.27, grain sorghum 0.22, sweet sorghum 0.18 lb. per head. A good deal of sorghum grain passed through the lambs whole, but the digestibility compared favourably with that of maize. Grinding the sorghum is unnecessary and uneconomical.

The grain was highly palatable and should be used where the sorghum crop is more reliable and yields more heavily than maize.—P. C. Jowsey.

2518

DICK, A. T. **Influence of inorganic sulphate on the copper-molybdenum interrelationship in sheep.** *Nature*, 1953, 172, 637-638. [Div. Animal Health Prod., Animal Health Res. Lab., C.S.I.R.O., Parkville, N. 2, Victoria, Australia.]

In sheep on a diet of chaffed alfalfa hay and chaffed oat hay, Mo intake limited storage of Cu in the liver. The effect was greater when the diet consisted of chaffed alfalfa hay, and was not observed in sheep on a diet of oat hay. The difference between these hays in their effect on the control of Cu storage by Mo was shown to be due to their different contents of inorganic sulphate. Alfalfa hay contained about 0.3 per cent., about 10 times the amount in oat hay.—F. C. Aitken.

2519

COOP, I. E. **Wool growth as affected by nutrition and by climatic factors.** *J. Agric. Sci.*, 1953, 43, 456-472. [Canterbury Agric. Coll., Univ. New Zealand.]

Groups of wet and dry ewes were used to study the effect of nutrition and season on wool growth. The weight, length and diameter of wool were estimated at monthly intervals. Some of the ewes were maintained on pasture and some in stalls, at sub- or super-maintenance levels. The observations were made for 3 years, and were considered in 4-monthly periods, pregnancy, lactation and the period from weaning to mating. Feeding levels were changed according to these periods. The wet ewes lambed in the spring.

There was a definite seasonal rhythm in the growth of wool, which was a maximum in summer and reduced to about a third in the winter. Reduction in weight of wool was due to reduction in both length and diameter. The amplitude of the seasonal variation was influenced by the level of nutrition, but the variation could not be eliminated. The reproductive cycle modified the effect of nutrition. In wet ewes the nutritional demands of pregnancy tended to reduce the rate of wool growth, and those of lactation delayed the rise, compared with dry ewes on the same level of nutrition at the same period. Within limits the level of nutrition modified the maximum and minimum of wool growth. There was no correlation between gain or loss of effective liveweight and wool growth. Subsidiary experiments on light and environmental temperature showed that these had a slight effect on wool growth, but did not eliminate the seasonal variation.—T. D. Bell.

CHOMYSZYN, M. and BIELIŃSKI, K. Wypas wybrakowanych owiec-matek. [Feeding of culled ewes.] *Rocz. Nauk rol. [B]*, 1953, **66**, No. 3, 43-56. Russian and English summaries.

Culled ewes were fed on pasture for 90 days, one group receiving 530 g. ground barley per head daily. At the beginning of the experiment 3 animals, and after 1, 2 and 3 months 2 animals from each group were killed and carcass quality was estimated. The group receiving no supplement gained 7.2 kg. in 60 days, and 7.3 kg. in 90 days. For the other group the figures were 5.6 and 6.9. There was no appreciable difference between groups or between periods in carcass quality. Utilisation of the pasture was poorer when the supplement was given. It is suggested that the grazing period could be shortened to 2

months, since there is little gain during the last month. (From summary.)—T. D. Bell.

2522

MEREGALLI, A. I risultati dei controlli funzionali negli ovini sardi per le annate 1949-50 e 1950-51. [Results of milk recording of Sardinian ewes during 1949-50 and 1950-51.] *Riv. Zootec.*, 1953, **26**, 268-269.

The number of sheep recorded in the Sarda flockbook at Cagliari is increasing, and new breeding centres are entering. As a result the performances recorded for 1950-51 are not so good as those for 1949-50, because selective breeding at the new centres has not progressed so far as at the old. There is considerable improvement on previous years, however. Milk yield and fat percentage are increasing, and selection of ewes for these characteristics is systematically practised. Recording of the performance of rams has also been initiated and this will lead to further efficiency from selective breeding.—T. D. Bell.

GREGORY, K. E. and DICKERSON, G. E. Influence of heterosis and plane of nutrition on rate and economy of gains, digestion and carcass composition of pigs. *Missouri Agric. Exp. Stat. Res. Bull.* No. 493, April 1952, pp. 48. [Columbia, Mo.]

As previous experiments had shown that heterosis in pigs increases growth rate but also increases appetite, it was desirable to study the effects of heterosis independently of feed consumption. The object of the experiment reported was to learn how heterosis affects rate and economy of gain and carcass quality under full feeding and when the feed intake of the crosses is restricted to that of the parent strains. During the experiment data were also obtained on digestibility and the general effects of limited feeding.

Limiting the feed intake to 87 per cent. of full feeding had no detectable effect on digestibility of dry matter, but reduced daily gains and decreased the feed required per unit of gain. The limited-fed pigs carried more lean meat and less fat, but had lower dressing percentages. The financial benefit of improved carcass quality was counteracted by this lower yield of dressed carcass.

When their feed consumption was limited to that of the parent strains the linecross and top-cross pigs grew from 13 to 26 per cent. faster and

from 9 to 19 per cent. more economically than the parent strains. The topcross pigs had better carcass qualities than the mean of the parent lines, for they carried more muscle and less fat.

When feed consumption was unrestricted, hybrid vigour expressed itself in greater feed consumption and more rapid and economical gains.

Breed had no effect on the digestibilities of the rations.—I. Lucas.

2527

VERBEEK, W. A. **New method of feeding pigs cheaply.** *Farming in S. Africa*, 1953, **28**, 311–312. [Dept. Animal Husb., Potchefstroom Coll. Agric.]

The method is to hand-feed 2 lb. per pig daily of a high-protein mixture (25 per cent. crude protein and 3 per cent. fibre) containing animal protein, and supply a high-fibre mixture (12 per cent. crude protein and 11 per cent. fibre) to appetite in self-feeders. The pigs need only be fed once a day, so there is a saving on labour, and it is claimed that the method produces good lean pork carcasses and ensures full utilisation of the expensive protein concentrates.—T. D. Bell.

2528

WUSSOW, W., WENIGER, J. H. and SCHUMM, H. R. Die Wirkung einer APF-Beigabe auf Futterverwertung und Schlachtleistung bei Schweinen. [Effect of an APF supplement on feed utilisation and carcass weight of pigs.] *Arch. Tierernährung*, 1953, **3**, 223–239. [Inst. Tierzucht, Martin Luther Univ., Halle, Wittenberg.]

The animal-protein factor supplement was Beta-meal, a by-product from the manufacture of fish-meal. The basal ration consisted of 300 g. barley meal, 400 g. ground oats, 300 g. wheat bran and potatoes to appetite. Eight groups of 4 pigs each were fed from 40 to 130 kg. liveweight, some control animals being killed at the start for carcass analyses. The 8 groups received the basal ration alone or with 80 or 40 g. Beta-meal, 200 g. yeast alone or with 40 g. Beta-meal, 300 g. peameal alone or with 40 g. Beta-meal, and 150 g. meat-meal.

The greatest daily liveweight gain was shown in all the groups receiving the Beta-meal and there was no significant difference between the results with 80 and 40 g. Apart from the meatmeal group the feed intake per kg. liveweight gain was lowest when Beta-meal was given. The slaughter tests and analysis of the carcasses showed a better feed utilisation with Beta-meal. In the internal organs the only effects noted were an increase in liver weight and length of the large intestine in the Beta-meal group animals. These results are in agreement with earlier findings of Fischer

(*Tierzucht*, 1951, p. 32) and Stahl *et al.* (*ibid.*, 1952, p. 155).—W. Godden.

2529

HANSON, L. E., BAKER, M. L., BAKER, G. N. and RUMERY, M. G. A. **Distillers solubles in market pig rations.** *Nebraska Agric. Exp. Stat. Bull.* No. 415, November 1952, pp. 19.

The literature is reviewed and 7 feeding trials are reported.

In 2 trials distiller's solubles successfully replaced part or all of the tankage in rations containing soya bean meal and 5 or 10 per cent. alfalfa. In the next 3 trials solubles were used as a substitute for alfalfa meal, soya bean meal or tankage, or as a supplement to a mixture of these. The solubles were satisfactory when replacing soya bean meal or tankage, but not alfalfa meal, especially when this was of high grade. As an addition to the mixture, solubles had no advantage. The last 2 trials used the same protein mixtures as the previous 3, mixed with yellow maize, to supply rations of equal protein content. Rates of gain were similar in all groups, but were not considered satisfactory.—T. D. Bell.

BREIREM, K., HUSBY, M. and HVIDSTEN, H. Varmedbehandling av soyamel og soyakakemel. [Heat treatment of soya bean meal and soya bean cake meal.] *Tidsskr. norske Landbruk*, 1953, **60**, 227–241. [Landbrukshøgskole.] English summary.

In Norway "soyamel" commonly means the residue from solvent extraction with about 1 per cent. fat and "soyakakemel" the residue from pressure extraction with about 5 per cent. fat. Published reports on the effect of heat in each process are reviewed. An experiment is described (part of a series to be published) with 5 groups of pigs on a cereal ration with cod liver oil and a salt mixture; as protein 3 had herring meal with or without herring solubles, 1 had 80 per cent. solvent-extracted soya meal with 20 per cent. fish solubles and the last solvent-extracted meal alone. Slaughter weight was 90 kg. Daily weight gains, corrected to 75 per cent. of slaughter weight, were 701 g. for the 3 herring meal groups together, 578 g. for the soya and fish solubles and 523 for soya alone. A second similar experiment gave similar results. In a third test herring meal, solvent-extracted soya meal as bought, and the same after cooking for 20 min. like porridge, and American expeller-process meal were compared. The pigs on soya meal alone lost appetite and did not reach 90 kg. slaughter weight. Corrected daily gains in the above order were 636, 493, 565 and 616 g. and feed consumption per unit gain

N.A. and R., April 1954

varied inversely with rate of gain. It is suggested that Norwegian soya meals do not have sufficient heat applied in the milling process and that additional boiling for 20 min. is also insufficient.

FAGAN, V. J., GIBLIN, A. G. and HOOPER, R. M. **Pig raising—experimental work. 2. Tasmanian J. Agric.**, 1953, **24**, 221–229. [Cressy Res. Farm.]

For part 1 see Abst. 3715, Vol. 23.

An experiment was made to test the value of penicillin in increasing the growth rate of normal weanling pigs on a normal ration. Groups of 10 pigs were used and the treatment was continued for 100 days. Group 1 had $\frac{1}{4}$ oz. procaine penicillin per 10 pigs daily; group 2 the same with an intramuscular injection of 1 ml. vitamin B₁₂ at the start of the experiment; half of group 3 had an initial intramuscular injection as in group 2, but no penicillin, and the other half had an initial injection of 2 ml., repeated monthly, and no penicillin. Group 4 acted as control, receiving the normal ration of crushed wheat and meatmeal to appetite, and skimmed milk.

The penicillin increased the appetite of the pigs, but no significant difference in rate of gain or efficiency of feed utilisation was observed between groups, and general health was the same. Conditions under which spectacular results from the use of antibiotics should not be expected are outlined.

In the second experiment there were 2 groups, one receiving swill and barley, and the other swill and barley plus $\frac{1}{4}$ lb. meatmeal per head daily. There were 8 weanling pigs in each group, and the trial lasted 72 days. The pigs receiving meatmeal gained faster than the others, but the difference was not significant. The experiment was repeated with 2 more groups of pigs fed for 60 days, with confirmatory results.

The economics of giving dry crushed or whole wheat from weaning to bacon weight was investigated in a trial with Berkshire sows and boars. Two groups of 6 pigs each received $\frac{1}{4}$ lb. meatmeal per head daily and wheat to appetite. For 1 group the wheat was crushed in a hammer mill, and this group gained faster than the whole wheat group. Even when the cost of crushing was set against that group, the financial return was greater.—T. D. Bell.

ZNANIECKI, P. Tucz trzody chlewnej paszą pochodzenia wyłącznie roślinnego. [Fattening of pigs with plant food only.] *Rocz. Nauk rol. [B]*, 1953, **66**, No. 1, 45–82. [Inst. Zootech. Z. D. Czechnica.] Russian and English summaries.

Comparison was made between groups of pigs receiving animal or plant protein. On plant protein only resistance to disease was reduced, efficiency of feed utilisation and rate of liveweight increase were less, and protein was not used so efficiently. There was not much difference in carcase quality, but there was greater variation within the group fattened on plant protein. (From summary.)—T. D. Bell.

Well-manured permanent pasture can supply 50 per cent. of the protein requirements of growing pigs, and 80 per cent. for fattening. Sows in early pregnancy can be maintained without supplements. The composition and use of pastures in Silesia were studied, and the results are reviewed. (From summary.)—T. D. Bell.

2536

GUNNING, O. V. Apples as a pig food. *Brit. Vet. J.*, 1953, **109**, 479–481.

No references have been found to substantiate the popular claims that apples are harmful to pigs. They may have no place in fattening, but breeding gilts on pasture in an orchard, given a small ration of dry meal and eating up to 20 lb. a day of apples, thrive and farrowed normally. For a short period they were fed indoors. Nursing was satisfactory, and the litters also utilised the apples well without ill effect.—T. D. Bell.

BEESON, W. M., PERRY, T. W. and REYNOLDS, P. J. **The effect of surfactants on the growth rate of swine.** *J. Animal Sci.*, 1953, **12**, 619-622. [Dept. Animal Husb., Purdue Univ. Agric. Exp. Stat., Lafayette, Ind.]

Two trials were made with Duroc weanling pigs. In the first the addition of 0.1 per cent. Ethomid C-15 to a basal ration had little effect on growth rate.

In the second trial the addition of 0.2 per cent. alkyl benzene sulphonate produced a significant increase in growth rate over a control group and the rate of growth was similar to that of a group receiving 7.5 mg. aureomycin per lb. feed. Lower levels of alkyl benzene sulphonate had no significant effect on growth.—J. S. Thomson.

2540

HEADY, E. O., WOODWORTH, R. C., CATRON, D. and ASHTON, G. C. **An experiment to derive productivity and substitution coefficients in pork output.** *J. Farm Econ.*, 1953, **35**, 341-351. [Iowa State Coll.]

Duroc and Duroc \times Landrace \times Poland pigs, 192 in all, were fed from about 40 lb. to 200 lb. weight on rations containing different proportions of No. 2 yellow maize and soya bean meal, with 500 mcg. vitamin B₁₂ per 100 lb. soya bean meal, and with or without 500 mg. aureomycin per 100 lb. feed. All rations contained, per 100 lb., bone-meal 3 lb., CaCO₃ 0.6 lb., trace minerals 0.1 lb. and vitamins 10 g. The pigs were weighed fortnightly and gains and feed intakes were recorded.

Two types of equation were fitted to the data, Y , the weight gain, being expressed either as a quadratic function of C and P , the respective amounts of maize and soya bean, or as a Cobb Douglas function of the form aC^bP^c , which logarithmic transformation renders linear. The equations of both types are given for rations with or without aureomycin for the ranges 40 to 75, 75 to 150 and 150 to 200 lb. and for the overall range. From these the marginal pork production from an extra pound of one feed when the other feed is (1) increased in the same proportion or (2) held constant is obtained by differentiation. Derived

tables are given showing the total gains and marginal gains for rations in fixed proportions with 12, 14 and 16 per cent. protein and with or without aureomycin, and for different total maize intakes with total protein intakes of 52 and 112 lb. Further equations are given from which can be found all possible combinations of the 2 feeds which will produce a given gain, and from these, again, substitution equations are obtained by differentiation. A derived table shows the combinations of protein and maize and the marginal rates of substitution of protein for maize for pigs weighing 60 and 75 lb., with aureomycin. In general, aureomycin reduced the quantity of both feeds required per 100 lb. gain, but its effect on the maize-protein substitution rate was not established.

Finally, although the main object of this report was to demonstrate the usefulness of co-operation between animal nutrition experts and production economists, the question arises how the results are to be presented to the farmer. A simple clock-face diagram for this purpose is illustrated.

Fuller details will be published later. A study of carcass composition on the different rations is in progress.—W. M. Deans.

BISHOP, G. R. H. **Breeding for bacon production.** *Minist. Agric. and Fish. Bull.* No. 158, H.M.S.O., London, 1953, pp. iv + 27. Price 1s. 9d. net.

General advice is given on selection, breeding and management for the production of bacon carcasses. Feeding is discussed only in general terms. The snags of selection for particular characters are pointed out, and the importance of the boar as well as the female stock is stressed. The advantages of pure breeds and crosses are discussed. There is a constant cry for the establishment of an efficient recording and testing scheme, the *sine qua non* of any successful development of bacon production based on selection.—T. D. Bell.

PARTANEN, J. Sikakantoja vertailevien kokeiden tulokset vuodelta 1951. [**Results of pig recording in Finland in 1951.**] 1953, pp. 24. [Tikkurila.] German summary.

In this scheme normally 2 gilts and 2 boars from a litter were sent to the experimental station when they were about 2 months old and weighed 15 to 20 kg. All pigs were then fed and housed alike and were slaughtered at about 90 kg. weight. The results from 265 Yorkshire, 42 Finnish Landrace and 8 Yorkshire \times Landrace pigs are reported. Losses of weight at slaughter were 24.6, 24.2 and 26.5 per cent., average daily liveweight gains over

the interval 20 to 88 kg. were 709, 733 and 772 g. and average feed requirements per kg. liveweight gain over the period were 3.27, 3.11 and 3.18 feed equivalent units (Hansson). Carcasses were graded for hardness, distribution and thickness of back fat and quality of belly muscle and hams, as well as being given points for liveweight gain and feed consumption. Of the 265 Yorkshire pigs 231 were graded class 1, 15 class 2, 4 class 3 and 15 class 4. For the 42 Landrace pigs the figures were 30, 6, 2, 4, and all the crossbreeds were graded class 1. (From summary.)—W. Godden.

GOATS, RABBITS AND OTHER MAMMALS

2545

PACHECO JORDAO, L. and CALDAS FILHO, C. F. Aspectos da eficiência reprodutiva dos caprinos, em São Paulo. [**Aspects of breeding efficiency of goats in São Paulo.**] *Bol. Indúst. animal, São Paulo*, 1952, **13**, 79–97. [Div. Zootec. Nutrição Animal.] English summary.

The goat population of Brazil at the 1940 census was 6.5 million on 361,000 farms. São Paulo had 139,000 on 30,000 farms. In 1950 the goat population of São Paulo was nearly 384,000. In the east and north of the country the goats are kept mostly for skins and meat; in the centre and south milk also is produced. The Department of Animal Production of São Paulo has registered 20 proprietors of 278 goats, mostly Toggenburg, which produce milk for sale in the capital. Mean daily yield is about 1 litre.

The breeding data discussed refer to 1176 goats, of which 589 were of indigenous breeds and crosses and the rest Toggenburg and Anglo-Nubian purebred and crosses and a few purebred Saanen and Angora.

Of purebred goats bred during the usual season, August to December or January, 71.2 per cent. conceived; outside this season, 78.7. For crosses the figures were 85.3, 93.8. Services per conception in the same order were 1.40, 1.27, 1.17 and 1.07. The mean number of young per gestation was 1.76.

EATON, O. N., SIMMONS, V. L., SYKES, J. F., WRENN, T. R. and HALL, S. R. **A study of the effect of stilbestrol induced lactation on dairy goats.** *J. Dairy Sci.*, 1953, **36**, 1089–1096. [Bur. Animal Indust., U.S. Dept. Agric., Washington, D.C.]

The purpose was to determine whether the future performance of dairy goats could be predicted from an early induced lactation.

Female Toggenburg kids born into the goat

herd of the Bureau of Animal Industry were divided into 2 groups. When the kids of 1 group were 13 to 16 months of age subcutaneous injections of 0.5 mg. diethylstilboestrol in 1 ml. oil were administered 3 times weekly for 50 days. The other group was untreated.

Twice-a-day milking was begun when production reached 1 lb. daily and was discontinued when it fell below this amount. The animals of both groups were bred in the autumn whenever oestrus was evident. The response to treatment was variable. The best producers were in lactation for 5 to 6 months. Some animals did not respond. Lactation curves for the induced lactation resembled those for a normal lactation, except that production was at a lower level. In general animals which were good producers under induced lactation proved to be good producers in their natural lactations.

It is concluded that extremely high and extremely low producers can be identified with a high degree of certainty.—J. N. Aitken.

2547

TEMPLETON, G. S. **Effects of certain methods of feeding and managing rabbits in commercial fryer production.** *U.S. Department of Agriculture Circular No. 901*, March 1952, pp. 16. [U.S. Rabbit Exp. Stat., Fontana, Calif.]

Forty-eight New Zealand white does and their 278 litters of 2107 young were studied over 19 months. From weaning at 2 months until they were mated and placed on test at 6 months, the young of both sexes were given daily 2½ oz. stock pellets and alfalfa hay to appetite. The stock pellets contained, in lb., soya bean meal 500, linseed meal 100, alfalfa meal 1200, mill run 400, barley 500, oats 100 and salt 15. The percentage composition was: crude protein 20.8, fat 3.7, fibre 15.1 and minerals 6.8. Herd bucks were continued on the same rations but does received

the hay only for about 14 days after mating. For the rest of the gestation period they received 4 oz. pellets daily and alfalfa hay to appetite.

Hopper and hand feeding were equally satisfactory and the former saved labour. With both methods the young weighed on the average 3.89 lb. at 56 days of age. From birth to 56 days, 22 per cent. of the young died, and a further 2.77 per cent. died between the 57th and 64th days.

From time of mating until the litters were weaned at 56 days, 4 lb. feed were required to

produce 1 lb. fryer and 5.39 lb. feed to produce an additional pound from the 57th to the 64th day.

TITUS, H. W., MEHRING, A. L. (Jr.) and BRUMBAUGH, J. H. **Variation of feed conversion.** *Poultry Sci.*, 1953, **32**, 1074-1077. [Lime Crest Res. Lab., Limestone Products Corporation of America, Newton, N.J.]

(The authors suggest that the term "feed efficiency" or "efficiency of feed utilisation" of a growing animal should mean the weight gain per unit weight of feed consumed. "Feed conversion" should be used as the reciprocal expression, the feed required per unit weight of gain made.)

A statistical study was made of 20 feeding experiments with duplicated groups, each containing 20 New Hampshire chicks. They were kept from day-old to 5 weeks of age in battery brooders in an air-conditioned room at 75° F. and were

then transferred to a battery in a room at 70° F. until they were 10 weeks old.

Only in 2.5 per cent. of the 156 groups considered did mortality exceed 3 per group. In 6 per cent. of the duplicate lots the difference between the feed conversion efficiencies exceeded 0.35, and in 17 per cent. it exceeded 0.2. The standard deviation of feed conversion to the age of 10 weeks for small groups of chicks (17 to 20) was estimated to be 0.1.—K. J. Carpenter.

2554

FISHER, H., SINGSEN, E. P. and MATTERSON, L. D. **The influence of feed efficiency on the phosphorus requirement for growth and bone calcification in the chick.** *Poultry Sci.*, 1953, **32**, 749-754. [Poultry Dept., Storrs Agric. Exp. Stat., Univ. Connecticut.]

Two rations of similar constitution but providing 968 and 683 Cal. per lb. were each given to 6 groups of 25 day-old New Hampshire × Barred Rock male chicks with 6 different levels of P, namely, 0.24, 0.35, 0.40, 0.45, 0.50 and 0.60 per cent. The basal rations contained similar amounts of Ca and P and a Ca : P ratio of 2 : 1 was always maintained by supplying lime with the extra NaH_2PO_4 .

The bone ash (left tibia) of 7 birds from each group was estimated at 2 and 4 weeks of age and indicated that the birds receiving the high-energy ration were utilising the feed P more efficiently; 0.51 per cent. P in the high-energy ration allowed as good calcification as 0.58 per cent. P in the low-energy ration. Increasing the P content of the ration had no effect on liveweight increase. Data on blood P values are recorded.—M. J. Head.

2555

WILCOX, R. A., CARLSON, C. W., KOHLMAYER, W. and GASTLER, G. F. **Calcium and phosphorus requirements of poults fed purified diets.** *Poultry Sci.*, 1953, **32**, 1030-1035. [Dept. Poultry Husb., S. Dakota Agric. Exp. Stat., College Station.]

Day-old Beltsville Small White Turkey poult were used to 4 weeks of age. The basal purified ration contained all the known poult nutrients in excess of known requirements, except Ca and P, which were provided at levels of 0.04 and 0.03 per cent., respectively.

In the first series of trials, the Ca level was raised to 2 per cent. and the P level ranged from 0.4 to 1.6 per cent. A supplement of 2 per cent. dried buttermilk produced increased growth over the purified rations, and an additional supplement of 1 per cent. forage juice increased this even further. On all diets the percentage bone ash rose with P supplementation up to the 1.2 per cent. level but then fell slightly. Generally, percentage bone ash was higher in birds receiving dried buttermilk and higher still in those receiving forage juice as well.

In the second series, both supplements were given to all groups; the P levels ranged from 0.6 to 1.2 per cent. and the Ca levels from 1.0 to 3.0 per cent. Maximum growth was obtained with 2 per cent. Ca and 1 per cent. P, but maximum bone ash was obtained with 1.3 per cent. Ca and 0.8 per cent. P.

In all experiments, a feed efficiency of 1.66 was found for the purified rations and of 2.05 for a ration of practical type used at the same time.

2556

O'NEIL, J. B. and SPINKS, J. W. T. **The relationship between the density of the fresh egg and calcium uptake in the chick.** *Poultry Sci.*, 1953, **32**, 919. *Proc.* [Univ. Saskatchewan, Saskatoon.]

2557

HEYWANG, B. W., BIRD, H. R. and KEMMERER, A. R. **The level of protein in the diet of growing New Hampshire chickens during hot weather.** *Poultry Sci.*, 1953, **32**, 781-785. [Agric. Res. Admin., U.S. Dept. Agric., Bur. Animal Indust., Glendale, Ariz.]

Experiment 1 was made at average daily maximum, minimum and mean temperatures of 102°, 76° and 89° F. Increasing amounts of soya bean oil meal were added to the rations of groups of 100 day-old New Hampshire chicks to give total protein contents of 20.1, 22.3, 24.3, 26.5 and 28.5 per cent. The average group liveweights to 10 weeks of age were 867, 914, 942, 958 and 946 g., with feed efficiencies 0.346, 0.358, 0.352, 0.330 and 0.312, respectively. Experiments 2 and 3 were made at average daily maximum, minimum and mean temperatures of 100° and 100° F., 71° and 72° F. and 86° and 85° F. Increasing amounts of sardine meal and casein were added to the rations of groups of 60 chicks to give total protein contents of 20.3, 22.6, 24.8, 26.9 and 29.1 per cent. The

liveweights at 10 weeks of age in experiment 2 were 914, 917, 929, 979 and 952 g., with feed efficiencies of 0.434, 0.446, 0.450, 0.478 and 0.463, respectively. In experiment 3 the average group liveweights were higher than in experiment 2, but feed efficiencies were lower at 0.394, 0.399, 0.432, 0.433 and 0.432. Experiment 4 was made in cool weather with average daily maximum, minimum and mean temperatures of 72°, 46° and 59° F. The rations were similar to those in experiments 2 and 3 but average group liveweights at 10 weeks of age were 1374, 1382, 1430, 1353 and 1387 g., with feed efficiencies of 0.408, 0.414, 0.413, 0.416 and 0.406, respectively.

No conclusion was drawn about the effect of hot weather on the optimum protein content of the ration. High temperatures had an adverse effect on feed consumption and weight increase.

ACKERSON, C. W. and MUSSEHL, F. E. **The utilization of food elements by growing poults. 2. A comparison of diets containing 25 and 30 percent. protein.** *Poultry Sci.*, 1953, **32**, 958-960. [Dept. Agric. Chem., Univ. Nebraska, Lincoln.]

The individual birds in groups of 32 day-old Beltsville Small White poults were given pelleted rations containing 24 or 30 per cent. protein. Each bird was killed after it had consumed 900 g. feed and the carcass was analysed for N, Ca and P. The poults on the 30 per cent. protein ration ate their feed in a shorter time and put on more weight than those on the 24 per cent. protein ration, but the latter utilised N, Ca and P more efficiently. The average N, Ca and P contents of a 5-week old poult were 3.30, 0.96 and 0.63 per cent., respectively.—M. J. Head.

2560

MENGE, H., DENTON, C. A., BIRD, H. R. and COMBS, G. F. **Effect of supplemental DL-methionine and varying protein levels on growth and feed requirements of broiler chickens.** *Poultry Sci.*, 1953, **32**, 827-836. [Bur. Animal Indust., U.S. Dept. Agric., Beltsville, Md.]

Similar experiments were made at 2 centres with 90 and 60 chicks per group, respectively.

The first part of the experiment covered the period from 0 to 6 weeks of age. Four groups of males, 4 of females and 2 of mixed sex were given a maize and soya bean type ration (A) with 22.4

per cent. crude protein with or without 0.05 per cent. DL-methionine. The supplement improved growth rate by about 5 per cent. and feed efficiency by 0.08 of a unit for males and females at both centres.

In the second part of the experiment, from the sixth to tenth week of age, the 5 groups that had received no methionine were redistributed on the basis of weight at 5 weeks into equal groups of both sexes. Each group then received the following rations: (1) ration (A); (2) ration (A) for 2 weeks, then a ration with 19.1 per cent. protein (B) for 2 weeks; (3) ration (B); (4) ration (A) for 2 weeks, then a ration with 15.8 per cent. protein (C) for 2 weeks; (5) ration (C). The groups receiving methionine were similarly redistributed. The overall effect of the methionine continued into this part of the experiment at only one centre, although chicks and feed from the same lot were used at both centres. Taking both centres together, no difference in average group gain was observed from the DL-methionine supplement, but feed efficiency was slightly improved. Growth rate was not affected by reducing the protein content of the ration to 15.8 per cent. during the sixth to eighth week, but feed efficiency was reduced. From the eighth to tenth week reduction of protein to 19.1 per cent. had no effect on growth; the highest feed efficiency was observed in those groups that were changed to this level of protein in the previous 2 weeks. Alteration in the total crude protein of the ration had no effect on the value of a methionine supplement. Comparison between sexes showed that males required a higher level of dietary protein for optimum growth from the eighth to tenth week than females.

MATTERSON, L. D., DECKER, L., SINGSEN, E. P., KOZEFF, A., WADDELL, J., HASBROUCK, C. J., BIRD, H. R., MENGE, H. and RUNNELS, T. D. **The value of supplemental methionine in practical chick starter and broiler rations.** *Poultry Sci.*, 1953, **32**, 817-826. [Storrs Agric. Exp. Stat., Conn.]

Similar experiments, with feed and chicks from the same lot, were made at 3 centres on a basal ration with supplements of 0, 2.5 and 5 per cent. menhaden fishmeal and 0, 1, 1.25 and 1.5 [unit not given] methionine per ton feed in a randomised block design. The results showed that between centres the weights of the birds in comparable groups were significantly different although the responses to the supplements were similar. Additional methionine to 8 weeks of age improved feed efficiency but had a variable effect on growth. Increasing the fishmeal to 2.5 per cent. improved both growth and feed efficiency, but the presence of fishmeal had no influence on the supplementary

effect of methionine. The effect of the methionine supplement was greater in chicks reared on a floor with litter than in those reared in a battery.

In 3 further experiments with supplements similar to those above but with different basal rations, the results showed different effects. A basal ration similar in composition to that in the above collaborative test but with ingredients from a different source produced a greater liveweight increase when supplemented with DL-methionine as above than without. The 1949-1950 New England College Conference high-energy ration had a similar effect, but the Connecticut Broiler Ration had not, although the feed efficiency was improved when it was supplemented with DL-methionine.—M. J. Head.

FANGAUF, R. and BARLÖWEN, G. v. **Methionin-zugaben im Kükenfutter. [Supplements of methionine in chick rations.]** *Arch. Geflügelk.*, 1953, **17**, 269-273. [Lehranst. Kleintierzucht, Kiel, Steenbek.] English summary.

In continuation of previous work (*Deutsche Wirtschaftsgeflügelzucht*, 1952, **4**, 149) 5 groups each of 30 day-old New Hampshire chicks were reared to 8 weeks on all-mash rations: (1) control, coarsely ground maize 30, ground wheat 30, wheat bran 15, alfalfa hay meal 3, dried yeast 3, cod fishmeal 8, soya grits 8, CaCO_3 1.2, Ca phosphate 1.2, salt 0.6, Dohyfral extra A + D₃ 0.02 per cent.; (2) methionine-low, the same except for the cereals, which were maize 20, wheat 15, barley 40 per cent.; (3) the same with 0.15 per cent. of DL-methionine; (4) methionine-low, maize 30, wheat 30, bran 13, cod fishmeal 4, soya grits 14, other items as in (1), with addition of 0.02 per cent. of a vitamin B₁₂ supplement containing 6 mg. vitamin B₁₂ per lb. and 0.22 per cent. of a penicillin supplement containing 2 g. penicillin G per lb.; (5) the same with 0.15 per cent. of DL-methionine. The chicks were weighed and feed eaten was measured weekly.

The results are tabulated and weight gains are shown graphically. The final mean weights in g. were 620, 583, 584, 645, 716, respectively. It was concluded that the reduction of the fishmeal could be compensated for by supplements of vitamin B₁₂ combined with methionine; the part played by penicillin is still open to question. The fact that methionine did not improve the barley ration indicates that poor growth on that ration was not due to the low methionine content of barley but to some substance present in barley.—W. M. Deans.

PATRICK, H. **The effect of processing method and certain supplements on a lysine deficiency in cottonseed meal for chicks.** *Poultry Sci.*,

N.A. and R., April 1954

1953, **32**, 942-944. [Dept. Poultry, Univ. Tennessee, Knoxville.]

In a series of 3 growth trials, chicks were fed from day-old to 5 weeks of age on a basal ration made up of cottonseed meal 30, ground oats 10, ground wheat 25, minerals 4.5, vitamin A and D concentrate, riboflavin, vitamin B₁₂ and maize-meal to 100.

The mean finishing weight of chicks receiving this ration made up with a "commercially prepared solvent-processed" cottonseed meal low in gossypol was 360 g., compared with the finishing weight of 437 g. of chicks receiving a similar ration containing a solvent-processed soya bean meal in place of the cottonseed meal. Chicks receiving the cottonseed meal ration supplemented with 0.5 per cent. lysine weighed 396 g. The substitution of a meal prepared in the laboratory by extraction of cottonseed with ether gave results similar, and the use of a hydraulic-processed meal gave results inferior to those obtained with the "commercial solvent" meal, both with and without the addition of lysine.

In a further trial final weights of 187 and 310 g. were obtained with the "hydraulic" and the "commercial solvent" meal, respectively. When 5 parts of cottonseed were replaced by other protein supplements the final weights were: with casein, 405 and 412 g., respectively; with soya bean oilmeal 334 and 424 g.; and with sesame seed meal 234 and 362 g.—K. J. Carpenter.

ATKINSON, R. L., REID, B. L., QUISENBERRY, J. H. and COUCH, J. R. **Antibiotics, methionine and unidentified growth factors in the nutrition of Broadbreasted Bronze turkey poults.** *J. Nutrition*, 1953, **51**, 53-64. [Dept. Poultry Husb., Texas Agric. Exp. Stat., College Station.]

A control group of 33 day-old poults, from a commercial breeding flock, were fed to appetite on a ration of soya bean meal 60, yellow maize-meal 35, minerals 5 and vitamins A, B₁₂, D₃, riboflavin, calcium pantothenate, nicotinic acid and choline chloride. At 8 weeks of age they had a mean weight of 1051 g. Parallel groups receiving the same ration supplemented with 11 p.p.m. bacitracin or 0.05 per cent. methionine were, respectively, 5 and 21 per cent. heavier. A further group receiving both supplements were on the average 35 per cent. heavier than the controls.

In a second, similar trial, a group receiving 11 p.p.m. aureomycin in their ration were, at 10 weeks of age, 2 per cent. heavier than the control group. Two more groups receiving a dietary supplement of 5 per cent. distiller's dried solubles (DDS) and a mixed supplement of aureomycin

and DDS, respectively, were 18 and 14 per cent. heavier than the controls.

On a modified control ration with 55 per cent. soya bean meal and ground milo in place of yellow maize-meal, 48 poults had a mean weight of 1222 g. at 8 weeks of age. Groups receiving 4.4 p.p.m. penicillin or 11 p.p.m. bacitracin were 20 and 13 per cent. heavier. Groups receiving 5 per cent. of DDS, alone or in combination with either penicillin or bacitracin, were 0, 23 and 16 per cent. heavier than the control group. In a further trial with similar conditions the addition of bacitracin again stimulated growth above that on the control ration, but had little effect when added to a ration already supplemented with DDS.

In a last trial with poults from a breeding flock fed on an experimental ration specially supplemented with sources of unidentified growth factors, the mean liveweight at 8 weeks of age of a group receiving the modified control ration was 1391 g. Groups receiving the same ration supplemented with 0.05 per cent. methionine or 5 per cent. DDS weighed 1533 and 1743 g., respectively. The addition of bacitracin or penicillin to these rations did not give consistently faster growth.

LILLIE, R. J., SIZEMORE, J. R. and BIRD, H. R. **Unidentified factors in poultry nutrition. 1. Development of chick assay.**

MENGE, H., DENTON, C. A., SIZEMORE, J. R., LILLIE, R. J. and BIRD, H. R. **2. Properties and preliminary fractionation of a growth factor in condensed fish solubles.** *Poultry Sci.*, 1953, **32**, 855-862; 863-867. [Bur. Animal Indust., U.S. Dept. Agric., Beltsville, Md.]

1. In the first and second experiments, it was found that New Hampshire male chicks were more sensitive than New Hampshire females, both sexes of Rhode Island Reds, or Beltsville Small White turkey poults to the presence or absence of unidentified growth factors in fishmeal. It was further shown that the basal ration of maize 61, soya bean 27, alfalfa meal 5 and fishmeal 4 was adequate in all known nutrients for growth.

With the technique evolved above, it was shown that fish solubles, fishmeal, wood yeast or dried

brewer's grains all contained a growth substance shown only to a small extent by dried whey. A combination of condensed fish solubles, wood yeast and dried whey produced a response similar to that of the fish solubles alone, indicating that each contained the same factor. Further experiments showed that meat-and-bone scraps, dried cells of *Torula utilis*, *Hansenula suaveolens* or *Bacillus subtilis*, dried sewage sludge, hatchery residues and dried poultry offal all increased the growth of chicks. In addition to dried whey, orotic acid and Bispar 'C' liver fraction had no such property, and dried *Streptomyces olivaceus* had only a slight effect.

2. The assay method used was that described in the previous section. It was shown that the growth factor in condensed fish solubles was stable when autoclaved for 30 min. at 15 lb. pressure at pH 2 to 11, but broke down at pH 1. When the condensed fish solubles were centrifuged at 1500 r.p.m. for 30 min., 3 layers separated, the top one being inert. The growth factor present in the remaining two-thirds was dialysable. It was found to be soluble in 50, 60 and 80 per cent. ethanol and 70 per cent. methanol but insoluble in ether. Using a two-phase water-phenol system it was possible to isolate substances active at concentrations of 0.04 to 0.055 per cent. of the ration, representing a concentration of 30 times compared with condensed fish solubles.

The addition of L-lyxoflavin or a mixture of amino-acids present in condensed fish solubles failed to give a growth response.—M. J. Head.

HILL, C. H. and KELLY, J. W. **The effect of antibiotics on the growth of chicks raised in new quarters.** *J. Nutrition*, 1953, **51**, 463–466. [Dept. Poultry Sci., Univ. N. Carolina, Raleigh.]

In a series of trials New Hampshire chicks from a commercial hatchery were grouped in wire-floored pens in a battery house not previously used for poultry, and were fed from day-old to 4 weeks of age on a control ration made up of soya bean meal 30, fishmeal 3, dried whey 3, alfalfa meal 3, methionine 0.2, vitamins, minerals and yellow maize meal to 100.

In the first trial the group fed on the control ration had a mean weight of 375 g. at 4 weeks, and that of a parallel group receiving the same ration supplemented with 22 p.p.m. crystalline aureomycin hydrochloride was not significantly different.

In the second trial the same cages were used, and only the dropping pens had been washed out. Again, a group receiving 22 p.p.m. aureomycin in their ration was no heavier than a control group; but a third group receiving 220 p.p.m. aureomycin was 10 per cent. heavier.

The same was found in a third trial with these 3 treatments in old, steam-sterilised cages in a new building.

It is concluded that a growth response may be obtained with chicks, even in new buildings and with new equipment, if large amounts of an antibiotic are given, and even though no response is obtained with amounts that give a response under farm conditions. It is suggested that organisms responsible for decreasing the growth rate of chicks

reared in new quarters may be more resistant to antibiotics than corresponding growth-retarding organisms met by chicks placed in quarters previously used.—K. J. Carpenter.

2576

WILSON, J. E. **The effects of penicillin supplements to the diet of turkey poults and chicks.** *Vet. Rec.*, 1953, **65**, 633-639. [Minist. Agric. Fish., Eskgrove, Lasswade.]

Turkey poults were reared from hatching to 4 weeks of age in wire-floored brooders and fed to appetite on a commercial dry "starter" mash. They were then transferred to solid floors and fed on "grower's mash", with a free choice of grain in addition after they were 12 weeks of age. In a series of 3 trials with 140 birds 47 per cent. died during the rearing period, and the survivors finished at 23 weeks of age with a mean liveweight of 6660 g. Parallel groups receiving the same treatment with the addition to their mash of 12 g. procaine penicillin per ton suffered only 14 per cent. loss and the survivors had a mean finishing weight 12 per cent. greater than that of the un-supplemented controls. The males receiving penicillin were 14 per cent. and the females 10 per cent. heavier than the corresponding controls.

The greatest effect of penicillin was observed in the first 4 weeks, when most of the deaths occurred, and at 4 weeks of age the supplemented birds were 51 per cent. heavier than the surviving controls. In further studies poults which had received penicillin only till they were 12 weeks of age gave a result not significantly different from parallel groups of birds that received the supplement from hatching to 23 weeks of age.

These trials were made in equipment that had been in use for several years. In short-term trials with new and isolated equipment poults with or without penicillin grew and survived as well as those raised in the old equipment and receiving supplementary penicillin.—K. J. Carpenter.

FELL, R. V. and STEPHENSON, E. L. **The effect of penicillin and penicillamine on chick growth when injected and when fed orally.** *Poultry Sci.*, 1953, **32**, 1092-1093. [Dept. Animal Indust., Univ. Arkansas, Fayetteville.]

Groups of 20-week-old White Wyandottes were given a basal ration containing 63 per cent. maize, 28 per cent. soya bean oilmeal, 4 per cent. fishmeal and 2 per cent. alfalfa meal, with adequate mineral and vitamin supplements. The following daily treatments were given: (1) nil; (2) 0.1 ml. saline injection; (3) 0.05 mg. penicillamine injection; (4) 0.1 mg. penicillamine injection; (5) 0.05 mg. penicillin injection; (6) 0.1 mg. penicillin injection; (7) 1 mg. penicillamine per lb. feed, by mouth;

(8) 1 mg. penicillin per lb. feed, by mouth, both substances dissolved in saline at a concentration of 1 mg. per ml. for injection and oral administration. The average gains to 3 weeks of age in duplicate experiments were: (1) 250 and 257, (2) 237 and 272, (3) 250 and 301, (4) 263 and 302, (5) 265 and 280, (6) nil and 287, (7) 248 and 294, (8) 254 and 274 g.—M. J. Head.

2578

STOKSTAD, E. L. R., JUKES, T. H. and WILLIAMS, W. L. **The growth-promoting effect of aureomycin on various types of diet.** *Poultry Sci.*, 1953, **32**, 1054-1058. [Lederle Labs. Div., American Cyanamid Co., Pearl River, N.Y.]

All the Barred Rock × New Hampshire chicks used were obtained from eggs laid by hens given a ration low in vitamin B₁₂. Duplicate groups of 10 to 12 day-old chicks were given a synthetic ration containing 20 per cent. casein, 8 per cent. gelatine and 60.5 per cent. carbohydrate as starch, sucrose, cerelese or lactose, with adequate mineral and vitamin supplements, including 5 µg. vitamin B₁₂ per 100 g. feed. Supplements of 100 mg. aureomycin and 100 g. liver residue (72 per cent. protein after hot-water extraction) per kg. feed were given singly or together.

The growth response to aureomycin was greatest on the sucrose ration and least on the starch ration. The growth response to the liver residue was greater with the starch and cerelese rations than with those containing sucrose. The growth with all rations containing lactose was poor. There was no effect on growth from the interaction of aureomycin and liver residue. With the antibiotic the time taken for feed to pass through the intestine increased from 126 to 184 min. on the sucrose diet, but the passage times of 180 min. for cerelese and starch were not affected.

In a further series of trials, 100 mg. aureomycin and 100 g. yeast per kg., separately or together, were given as supplements to a 30 per cent. and a 70 per cent. soya bean oilmeal ration and to a ration containing 25 per cent. of a sodium salt of purified soya bean protein. Both supplements improved growth; their effects were independent and additive. Yeast had no beneficial effect in the 70 per cent. soya bean ration.—M. J. Head.

2579

NORDSKOG, A. W. and JOHNSON, E. L. **Breed differences in response to feeding antibiotics.** *Poultry Sci.*, 1953, **32**, 1046-1051. [Iowa State Coll., Ames.]

A basal ration of mixed cereals, fishmeal and meat-and-bone scrap was used, supplemented with 1 mg. procaine penicillin or 4.5 mg. aureomycin per lb. feed. Birds from 3 hatches were used,

containing members of 9 breed types: (a) inbred: Leghorn and Heavy; (b) outbred: Leghorn, Rhode Island Red, Barred Plymouth Rock and Egyptian; (c) strain crosses: Leghorn; (d) top crosses: Leghorn; (e) crossbred: Heavy. During an 8-week experimental period, the antibiotics produced similar increases in growth, on the average 12.7 per cent. for all breeds; inbred Heavy and Egyptian outbred gave only a 6.3 and a 7.0 per cent. increase, but Barred Plymouth Rock outbred gave a 22.6 per cent. increase. These differences in breed liveweight response to antibiotic supplements were highly significant. Mortality was 3.7 per cent. with antibiotics and 9.1 per cent. on the control rations, a statistically significant difference, but there was no significant difference between breeds.—M. J. Head.

2580

MCGINNIS, J. and STERN, J. R. **Effect of the feed pelleting process on growth response of poults to antibiotic supplements.** *Poultry Sci.*, 1953, **32**, 1036-1038. [Dept. Poultry Sci., State Coll. Washington, Pullman.]

Groups of 10 day-old unsexed Broad Breasted Bronze poults were given a basal ration containing 42.7 per cent. ground maize, 10 per cent. herring meal, 37.8 per cent. soya bean meal, 2.5 per cent. dehydrated alfalfa, minerals and vitamins, with supplements of 1, 2 and 5 p.p.m. diamine penicillin, 1, 2 and 5 p.p.m. procaine penicillin and 2, 5 and 10 p.p.m. aureomycin, the antibiotics being added either before or after pelleting. In trial 1, pharmaceutical grade antibiotics were used, and in trial 2, commercial antibiotic feed supplements.

The results indicated that either form of penicillin produced a similar growth response at any dose level whether added before or after pelleting and irrespective of grade. Best results with aureomycin were obtained when it was added before pelleting, particularly at the 2 p.p.m. level. There was no difference in the response to the different qualities of aureomycin.—M. J. Head.

2581

DYMSZA, H., BOUCHER, R. V. and CALLENBACH, E. W. **The influence of antibiotic supplementation on certain physical and chemical characteristics of turkey poults.** *Poultry Sci.*, 1953, **32**, 989-993. [Dept. Agric. Chem., Pennsylvania State Coll., State College, Pa.]

Two groups of 90 day-old White Holland poults were given a basal ration of practical type with or without 10 g. terramycin per ton for a 4-week period. All chicks were killed, sexed and stored at 34° F. overnight before the physical measurements were made. The birds were then frozen at - 20° F. and ground for analysis.

The antibiotic increased liveweight by 11 per cent. and empty weight by 14.5 per cent., both differences being statistically significant. The weights of the empty intestinal tract less caeca, empty gizzard, empty caeca and contents of the alimentary canal from poults given antibiotic were 10.5, 10.9, 2.4 and 7.8 per cent. higher, respectively, than those of controls. It is thought that these data represent normal increases in growth because when expressed as percentage empty weight they are similar to those from the control birds. The carcasses of the birds given antibiotic had a higher percentage of dry matter; otherwise the composition was similar.—M. J. Head.

2582

JONES, H. L. and COMBS, G. F. **Effect of aureomycin HCl on the utilization of inorganic nitrogen by the chick.** *Poultry Sci.*, 1953, **32**, 873-875. [Dept. Poultry Husb., Univ. Maryland, College Park.]

Urea, ammonium citrate and dibasic ammonium phosphate, used as single supplements, failed to increase the value of low-protein chick rations, as judged by either growth rate or feed conversion efficiency of chicks in the first 4 weeks of life. This was true for rations with and without either 10 or 25 p.p.m. aureomycin hydrochloride.

K. J. Carpenter.

2583

HILL, C. H., BORCHERS, R. L., ACKERSON, C. W. and MUSSEHL, F. E. **Studies on chick growth stimulation by alfalfa juice, casein, and aureomycin.** *Poultry Sci.*, 1953, **32**, 775-779. [Dept. Agric. Chem., Univ. Nebraska, Lincoln.]

In a series of trials, groups of newly hatched chicks from breeding flocks fed on normal commercial rations were given a high-protein ration of soya bean meal 70, maize meal 23, methionine 1.1, minerals and vitamins. Two groups of chicks on this ration alone had a mean weight of 528 g. at 6 weeks; parallel groups on the same ration supplemented with 5 per cent. of a juice expressed from freshly cut alfalfa were 9 per cent. heavier. In a further trial a group on the control ration supplemented with 10 mg. aureomycin hydrochloride per lb. weighed 347 g. at 5 weeks, and a second group receiving the ration supplemented with both alfalfa juice and aureomycin was no heavier. Casein as a supplement to the ration appeared to stimulate growth in both presence and absence of aureomycin.

With a second control ration, similar to the first but with glucose in place of maize meal, the growth of groups receiving either supplementary aureomycin or alfalfa juice was similar to that of the group receiving this ration without supplement.

N.A. and R., April 1954

Faster growth was obtained with a group receiving both supplements.—K. J. Carpenter.

2584

SAXENA, H. C., BLAYLOCK, L. G., CARVER, J. S. and MCGINNIS, J. **Factors affecting the growth response of turkey poults to antibiotics.** *Poultry Sci.*, 1953, **32**, 788-791. [Dept. Poultry Sci., State Coll. Washington, Pullman.]

Newly hatched poults from dams fed on practical rations were housed in cages with raised wire floors. Three groups, each of 10 poults, were fed to appetite on a dry mash consisting of solvent-extracted soya bean meal 52.4, dried brewer's yeast 2, alfalfa meal 2.5, choline chloride 0.1, riboflavin, vitamins A and D supplement, minerals and yellow maize meal to 100. This ration was calculated to contain crude protein 28, Ca 2.1 and P 1.0 per cent. The poults had a mean liveweight of 480 g. at 4 weeks of age.

Further birds which received the same ration supplemented with 5 per cent. of herring meal, added at the expense of soya bean, maize and minerals so as not to alter the total contents of crude protein, Ca and P had a mean weight of 523 g. Groups receiving 2.5, 7.5 and 10 per cent. of herring meal in their mash weighed 470, 506 and 499 g. per head, respectively.

Poults receiving the control ration supplemented with 3 p.p.m. of diamine penicillin weighed 544 g., and those receiving both penicillin and 5 per cent. of herring meal weighed 655 g.—K. J. Carpenter.

2585

ALMQUIST, H. J. and MERRITT, J. B. **The value of antibiotic supplements for growth and feed conversion in diets for growing turkeys.** *Poultry Sci.*, 1953, **32**, 878-880. [Grange Co., Modesto, Calif.]

Turkey poults were divided at hatching into 5 groups each of 400 birds. A control group was fed on commercial mashes, all containing 5 g. aureomycin per ton, which declined in protein content from 28 per cent. for the first month to 20 per cent. after the birds reached 10 weeks. In 16 weeks the toms had a mean weight gain of 8.0 lb. and the hens of 6.0 lb.

In a similar group that received the same treatment with an additional supplement of 2 g. diamine penicillin per ton mash, the toms and hens finished with mean weights of 9.2 and 6.2 lb., respectively. Further groups received diamine penicillin for different portions of the growing period, and it was concluded that the toms showed a response in growth rate to this supplement at any period, but that they reverted to the normal growth rate when the supplement was removed.

K. J. Carpenter.

2586

WILSON, A. A. and EASTWOOD, B. **Experiences with the feeding of procaine penicillin to poultry.** *Vet. Rec.*, 1953, **65**, 665-668. [Res. Dept., Boots Pure Drug Co., Ltd., Thurgarton, Notts.]

A control group of 30 chicks was housed intensively and fed from day-old to 8 weeks of age on a commercial starting mash, and then on a commercial growing mash. Three parallel groups received the same treatment with the addition of 2, 4 or 10 g. procaine penicillin per ton feed. At 16 weeks of age the mean weight of the control birds was 4 lb. 7 oz., and that of those receiving penicillin was 7 oz. greater. There was no significant difference between the mean weights with the different levels of penicillin.

In a field trial with similar rations a control group of 170 cockerels had a mean weight of 3 lb. 10 oz. at 15 weeks of age, and 2 similar groups that had received 2.5 g. procaine penicillin per ton mash had a mean weight 4 oz. greater. In both these trials there was a tendency for feed conversion to be more efficient, by 3 to 6 per cent., in the birds receiving penicillin than in the controls.

A group of 27 poults was reared from hatching to 16 weeks of age on commercial rations and finished with a mean weight of 8 lb. 6 oz. Two further groups received the same treatment with supplements of 15 g. procaine penicillin per ton mash. All groups also received grain in amounts increasing to 50 per cent. of their total feed by the end of the growing period.

The turkeys receiving penicillin had a mean weight of 1 lb. 14 oz. above that of the control group. There was a tendency for the difference to be greater with the females than with the males. The control group and one group receiving penicillin were weighed again at 24 weeks of age; the latter were heavier by 2 lb. 3 oz.

K. J. Carpenter.

2587

KRÜGER, L., SEEFELDT, G. and LÖTHE, E. **Kükenaufzuchtversuche mit "Entan" und "Fortracin".** [Chick rearing experiments with "Entan" and "Fortracin".] *Arch. Geflügelk.*, 1953, **17**, 274-284. [Inst. Tierzucht, Justus Liebig Hochsch., Giessen.] English summary.

In the first experiment, 3 groups of 37 Leghorn cockerels were fed in batteries from 8 days to 9 weeks. For the first 5 weeks group 1 had a normal ration of coarsely ground barley, maize and milo each 20, fishmeal 22, dried skimmed milk 6, dried yeast 3, alfalfa meal 3, calcium carbonate 4 and wood charcoal 2 per cent., group 3 the same with 0.5 per cent. Entan, a preparation of vitamin B₁₂ and terramycin, replacing the same amount of milo, and group 2 the same as group 3 except that half the fishmeal and half the dried milk were

replaced weight for weight by soya grits. For the last 3 weeks group 1 had ground barley 5, maize 10, milo 20, wheat 25, groundnut meal 5, malt sprouts 5, meatmeal 8, herringmeal 5, dried skimmed milk 3, alfalfa meal 5 and other items as before, group 3 the same with 0.5 per cent. Entan replacing maize, and group 2 the same as group 3 with half the animal protein replaced by groundnut meal 4, malt sprouts 3 and dried yeast 1 per cent. The chicks were weighed and feed eaten was recorded weekly and the results are presented in tables and graphically.

Group 2 gained as well as group 1 and showed less of a check in growth when the ration was changed; feed utilisation was slightly better and feed cost less. On the other hand, no advantage resulted from addition of Entan to a ration containing a normal amount of animal protein.

In the second experiment 2 groups each of 40 cockerels were fed from 14 days to 10 weeks on a ration of ground barley 22, maize 13, milo 20, soya grits 20, dried yeast 3, dried skimmed milk 3, fishmeal 11, alfalfa meal 3, wood charcoal 2, calcium carbonate 1.95 and calcium phosphate 1.05 per cent., or the same with 0.3 per cent. Fortracin, a preparation of bacitracin, replacing ground maize.

The group with Fortracin made poorer gains, although towards the end they tended to catch up, and feed intake was slightly greater. Whether Fortracin would be of benefit when added to a ration with half the animal protein, or in conjunction with vitamin B₁₂, remains to be seen.

WHARTON, F. D. (Jr.) and FRITZ, J. C. **Studies on the effect of an arsenical in the diet of the immature and mature chicken.** *Poultry Sci.*, 1953, **32**, 1014-1020. [Dawe's Labs., Inc.]

Two groups of 126 day-old New Hampshire chicks were given to appetite a basal starter ration containing 48.8 per cent. maize, 10 per cent. middlings, 5 per cent. ground oats, 22.5 per cent. soya bean meal, 2.5 per cent. meat-and-bone meal, 1.25 per cent. fishmeal and 5 per cent. dehydrated alfalfa meal, with mineral and vitamin supplements. At 40 days of age the rations were changed to grower rations and at 23 weeks of age to layer rations containing antibiotic. A supplement of 2.27 g. *p*-hydroxyphenylarsonic acid per 100 lb. feed was given to one group; thereafter half the birds from each group reversed their "starting-growing" treatment.

The arsenical had no effect on growth at the level used, but the supplemented birds produced slightly heavier eggs and utilised their feed more efficiently. No effect was observed on fertility, hatchability, weight of chicks at hatching or growth of progeny. Eggs from the birds given arsenic during the laying period contained 0.21 p.p.m. As₂O₃ as against a control figure of 0.06 p.p.m.

N.A. and R., April 1954

Groups of 15 day-old Delaware \times New Hampshire pullets and a similar number of straight New Hampshire pullets were given rations containing 5, 15 and 45 mg. methyl testosterone per lb. feed; a further group of each breed was given 5 mg. methyl testosterone per lb. feed from the sixth to the tenth week only. A group of 15 cockerels was also carried through the experiment. Methyl testosterone had no effect on liveweight or feed conversion, but the pullet chicks developed bright red combs and wattles.—M. J. Head.

PEPPER, W. F., SLINGER, S. J. and SNYDER, E. S. **Value of low levels of soybean oil in broiler diets containing a high percentage of wheat.** *Poultry Sci.*, 1953, **32**, 1084-1086. [Dept. Poultry Husb., Ontario Agric. Coll., Guelph.]

A group of 125 day-old male chicks and a similar group of females were fed to appetite on a ration made up of soya bean oilmeal (solvent-extracted) 24, fishmeal 2.5, dried buttermilk 2, meatmeal 1, grassmeal 2, minerals 2.25, fish oil 0.25, riboflavin, 3-nitro-4-hydroxy-phenylarsonic acid, sulphaquinoxaline, a vitamin B₁₂ and penicillin supplement, DL-methionine, yellow maize meal and ground wheat to 100. After 6 weeks the chicks received a modified mash containing only 15 parts of soya bean oilmeal and additional maize meal. At 11 weeks the birds were killed. Their mean final weight was 1937 g. for the males and 1508 g. for the females, with feed conversions of 2.85 and 3.08 g. feed per g. gain, respectively.

Further groups receiving the same rations supplemented with 2 per cent. of soya bean oil at the expense of maize meal finished with mean weights of 1957 and 1553 g. and feed conversion quotients of 2.75 and 3.02, respectively. Parallel groups receiving 1 per cent. of oil also gave similar results. The mashes containing oil were less dusty and gave a better market finish than the control mashes.—K. J. Carpenter.

LEME DA ROCHA, G. and FRANCISCO RAIMO, H. F. **Contribuição ao estudo dos substitutos dos farelos de trigo na alimentação das aves. 2. Guandu. [Substitutes for wheat products in poultry feeding. 2. Pigeon peas.]** *Bol. Indúst. animal, São Paulo*, 1952, **13**, 119-129. [Div. Zootec. Nutrição Animal.] English summary.

A ration containing 35 per cent. of wheat products (bran plus middlings) served as control and the test ration was identical except that the wheat products were entirely replaced by pigeon pea (*Cajanus cajan*) flour. Groups of 45 New Hampshire chicks were used and the experiment lasted from birth to 30 weeks of age.

At 14 weeks the test group had an average liveweight of 1263.5 g. and the controls of 1384.8 g. The 2 groups had consumed on the average 7001.0 g. and 7463.9 g. feed, respectively. No significant difference in body conformation or feathering was noted between the 2 groups. From 14 to 30 weeks of age the test group ate less feed than the controls and finished at the same average liveweight. Sexual maturity was delayed about 6 days in the test birds compared with controls. A 48-day egg laying test showed that the test birds laid 7.64 per cent. more eggs than the controls.

It was concluded that pigeon pea flour is suitable for poultry.—P. C. Jowsey.

2603

WILD, H. and COOPER, G. H. **Mexican clover (*Richardia brasiliensis*) as a green feed for poultry.** *Rhodesia Agric. J.*, 1953, **50**, 192-194.

The moisture content of Mexican clover was 73.0 per cent. and its composition on a dry matter basis was: ash 13.3, protein 21.3, oil 1.9, fibre 25.5, N-free extract 38.0 per cent. The ash contained Ca 4.9, MgO 0.7, P₂O₅ 0.8, K₂O 3.3, SiO₂ 3.4 per cent.

All classes of poultry ate the chopped plant with relish and preferred it to chopped alfalfa to which they were accustomed. No adverse effect was observed when the plant was given with the usual concentrates for several months.—P. C. Jowsey.

[**Comparative trials in chick rearing from the point of view of veterinary hygiene and experiments in rearing on deep litter.**] *Berl. Münch. tierärztl. Wochenschr.*, 1953, **66**, 385-392. [Abt. Geflügelkrank., Humboldt Univ., Berlin.] English summary.

After a review of the literature the results of an experiment made in a manner similar to those of Mehner (Abst. 1114, Vol. 23) are reported. Four groups of 400 chicks each were used and the experiment lasted 8 weeks. Groups 1 and 2 were kept on a layer of chopped straw 5 cm. deep which was replaced at first daily and then weekly. Group 2 had under-floor heating. Group 3 was kept on a layer 25 cm. deep built up of alternate layers of old hen litter and old garden mould. Group 4 was kept similarly but fresh horse manure replaced the hen manure. There was little difference in liveweight gain or feed utilisation over the 8-week period; if anything, those in group 1 were poorer than those in the other groups. The results were in general agreement with those of Mehner and did not show any great advantage of deep litter.

HATHAWAY, H. E., CHAMPAGNE, G. B., WATTS, A. B. and UPP, C. W. **Meat yield of broilers of different breeds, strains and crosses.** *Poultry Sci.*, 1953, **32**, 968-977. [Dept. Poultry Indust., Louisiana State Univ., Baton Rouge.]

In 3 trials with 1800 chickens of both sexes in all, grown to 12 weeks of age, the meat yields of broiler and non-broiler strains of Dark Cornish, New Hampshire, White Plymouth Rock and cross-breeds were compared. Total edible meat, breast meat, New York dressed weight and eviscerated carcass weight of 350 carcasses were estimated, and keel length, body depth and breast width were measured.

Males were 20 per cent. heavier than females when 12 weeks old, and broiler strains were heavier than non-broiler. Dark Cornish yielded a higher

percentage of edible meat, followed by White Plymouth Rock, crossbreeds and New Hampshire. The Dark Cornish were lightest in liveweight but greatest in breast width, and gave more total edible meat.

Breast width was found to be the best single measurement for estimating the percentage of breast meat and the total edible meat yield.

FRANCISCO RAIMO, H. O marreco Pequim como produtor de carne. [**The Pekin duck as meat producer.**] *Bol. Indúst. animal, São Paulo*, 1952, **13**, 111-117. [Div. Zootec. Nutrição Animal.] English summary.

From birth to 9 weeks of age 29 White Pekin ducklings ate on the average 8056 g. feed per head and reached an average liveweight of 2255 g. At this age sex did not significantly affect liveweight.

Ten ducks of each sex were killed at 9 weeks of age. Dressed and drawn but with head and feet, the carcasses weighed on the average 80.6 per cent. of the liveweight; without head and feet they weighed 65 per cent. Edible meat was 69.6 per cent. of dressed weight.

The edible meat had the following composition: water 70.0, protein 22.7, fat 4.1, ash 3.1 and matter not estimated 0.1 per cent.—P. C. Jowsey.

2609

COLES, R. **The production of table poultry.** *J. Sci. Food Agric.*, 1953, **4**, 532-539. [Minist. Agric. Fish., 1-4 Cambridge Terr., Regent's Park, London, N.W.1.]

Weight gains and feed consumption were recorded weekly for 15 groups of Light Sussex cockerels, 5 of North Holland Blues, 2 of New Hampshires and 1 of Marans. Each group consisted of 30 purebred birds housed in a concrete-floored building on deep litter and each bird had 3 sq. ft. of floor space. They were fed from day-old to 20 weeks on a dry mash of ground grains, groundnuts and fishmeal with grassmeal, bone flour, vitamin D₃ and manganistat salt. Nitrofurazone was added as a coccidiostat.

The results are given in detail for each breed. The average growth rate increased to the tenth week when the average weight was 3.28 lb., the average total feed consumption 10.06 lb. and the cumulative feed conversion ratio 3.06:1. After the tenth week average growth rate declined until the 16th week, then increased substantially and continued to do so until the end of the test at 20 weeks. Carcass condition and fleshing quality improved to a peak at the end of the tenth week; fleshing quality declined thereafter.

The results indicated that birds not specially bred for the table may be successfully reared for this purpose. An 11-week-old bird weighing about

N.A. and R., April 1954

3½ lb. offers the best means of increasing the availability of poultry meat at a reasonable price to the consumer and with an adequate profit to the rearer. The cost of the feed given was taken to be 40s. per cwt. and on this basis a 3½ lb. bird at 11 weeks of age ate about 4s. 4d. worth of feed, equivalent to 1s. 2d. per lb. The feed cost per lb. of bird increased rapidly after the twelfth week. At 20 weeks the cost per lb. was on the average just over 2s. The large-sized roaster of about 6 lb. seems likely to remain within the luxury market.

EGG PRODUCTION

2615

GILLIS, M. B., NORRIS, L. C. and HEUSER, G. F. **Phosphorus metabolism and requirements of hens.** *Poultry Sci.*, 1953, **32**, 977-984. [Agric. Exp. Stat., Cornell Univ., Ithaca, N.Y.]

Groups of 15 to 16 White Leghorn hens in their first production year were fed to appetite. In experiment 1, a low-P, semi-synthetic basal ration was given alone or with supplements of defluorinated phosphate to provide inorganic P at levels of 0.70, 0.50 or 0.25 per cent. and supplements of Ca phytate to give phytin P levels of 0.05, 0.25, 0.50

and 0.75 per cent., giving a total P level of 0.75 per cent.; the Ca level was 2.0 per cent. for all groups. Group 1 receiving 0.70 inorganic P and 0.05 per cent. phytate P was discontinued after 4 of the 6 months of the experimental period. Mortality in group 4 was 60 per cent. and the survivors lost weight, showing that phytate P was less readily utilised than inorganic P; egg production, bone ash and blood P were also low in this group. Group 2 gave satisfactory performance in all respects; group 3 were satisfactory except for liveweight gain, eggshell quality and blood inorganic P.

In experiment 2, the total P level in both rations was 0.74 per cent., with phytin P at 0.53 and 0.29 per cent. Bran supplied the phytate P and was removed from the bran by enzyme action for the ration low in phytate P. The results indicated that there was no difference in the utilisation of naturally occurring or pure phytate.

In experiment 3, two basal rations were used, one high and one low in phytate P. Each was given alone or supplemented with 0.67 and 1.33 per cent. CaHPO_4 . The low-phytin ration contained 0.10 per cent. phytate P and the high 0.32 per cent. and the supplements were of 0.39, 0.54 and 0.69 per cent. inorganic P. Additional groups received 0.15 per cent. and 0.30 per cent. inorganic P with each ration.

The group receiving 0.49 per cent. total P including 0.10 per cent. phytate P gave satisfactory egg production and liveweight maintenance, but blood inorganic P remained subnormal. The ration containing 0.47 per cent. total P including 0.32 per cent. phytate P was considerably improved, by all criteria, by a supplement of 0.15 or 0.30 per cent. inorganic P.

It is suggested that in synthetic diets 0.65 per cent. total P as inorganic P gives satisfactory results but that the level should be raised to 0.77 per cent. when commercial rations are given, to allow for the relative unavailability of phytate P.—M. J. Head.

SCHMIDT, F. **Wpływ kazeiny jodowanej jako dodatku do karmy kurcząt na ich przyszłą**

nieśność. [The influence of iodised casein as an addition to the diet of pullets on their future production of eggs.] *Rocz. Nauk rol.* [B], 1953, 66, No. 2, 23-47. [Inst. Produkcji Zwierzęcej, Uniwers. Jagielloński.] Russian and English summaries.

Iodinated casein, 0.013 to 0.023 g. daily, was given to Rhode Island Red pullets for 86 days, when they started laying. There was no effect on age at maturity. After 50 days on treatment the general condition of the birds improved and liveweight increased. More eggs were laid per month but egg weight was not affected. Observations over 10 months' laying suggest that iodinated casein can effectively increase egg production on an adequate diet, at least in the first year. (From summary.)—T. D. Bell.

2619

BARBORIAK, J., JUCKER, H. and CRASEMANN, E. Über die Wirkung einer Rohleizithinzulage bei Legehennen. [Effect of a supplement of crude lecithin for laying hens.] *Arch. Geflügelk.*, 1953, 17, 245-259. [Inst. Haustiernährung, Tech. Hochsch., Zürich.] English summary.

In experiments at 2 centres with groups of White Leghorn pullets the addition of 4 per cent. of crude lecithin to a normal laying mash had no effect on the health or bodyweight of the birds, on the percentage of white, yolk and shell in the eggs or on the percentage of lecithin in the yolk. There was a slight but not significant increase in egg production and feed utilisation.—W. Godden.

2620

COONEY, W. T. and PARKER, J. E. Wood sugar molasses in the ration of floor managed layers. *Poultry Sci.*, 1953, 32, 1039-1046. [Oregon State Coll., Corvallis.]

The wood molasses used contained 50 per cent. sugar, of which 85 per cent. was hexose (mainly glucose) and 15 per cent. pentose (mainly xylose). The mash in which 7.5 or 15 per cent. of the molasses was incorporated formed 60 per cent. of the daily feed. Groups of 50 Single Comb White Leghorn pullets were used during a 334-day experimental period (September to July).

The birds receiving 7.5 per cent. wood molasses in the mash (4.4 per cent. of the total ration) produced 7 per cent. more eggs than the controls; the higher level had no effect on egg production, and feed efficiency was less. The wood shaving litter in the pen of birds receiving 15 per cent. wood molasses became sticky and difficult to handle and in consequence the number of soiled eggs was higher. The inclusion of molasses in the feed had no effect on bird mortality, liveweight gain or hatchability of eggs.—M. J. Head.

2621

ELAM, J. F., JACOBS, R. L. and COUCH, J. R. The effect of prolonged feeding of antibiotics upon the performance of laying hens. *Poultry Sci.*, 1953, 32, 792-795. [Dept. Biochem., Agric. and Mech. Coll. System, College Station, Tex.]

Ten pullet chicks were fed from hatching to 15 months on a ration of soya bean meal 35, with minerals, fish oil, riboflavin and Ca pantothenate, and yellow maize meal to 100. Each bird received also a weekly injection of 1 µg. vitamin B₁₂. At 15 weeks the birds were transferred from pens with raised screen floors to individual battery cages. In the last 9 months of the trial they gave a mean egg production of 56 per cent.

Similar groups that received in addition per kg. mash 33 mg. of bacitracin, penicillin or inactivated penicillin gave 62, 62 and 59 per cent. production, respectively. Groups receiving the same supplements by injection at the rate of 1.2 mg. per bird weekly gave 58, 60 and 58 per cent. production. Pullets that received an injection of 15,000 units of penicillin-in-oil on alternate days gave 62 per cent. production. All the pullets were artificially inseminated. Eggs from the unsupplemented group showed a mean hatchability of 79 per cent.; hatchability in the other groups ranged from 85 to 90 per cent.

In a parallel trial the same basal ration was used but none of the birds received vitamin B₁₂; egg production of the 10 control pullets was 46 per cent. and that of groups receiving bacitracin, penicillin or inactivated penicillin by mouth was 53, 53 and 44 per cent., respectively. Groups receiving the antibiotics by injection gave 46, 53 and 44 per cent. egg production. Hatchability was 53 per cent. in the control group and ranged from 43 to 66 per cent. in the other groups.—K. J. Carpenter.

FRANCISCO RAIMO, H. Estudo da produção de ovos na raça Pequim e suas principais características biológicas. [Egg production by Pekin ducks, and their chief biological characteristics.] *Bol. Indúst. animal, São Paulo*, 1952, **13**, 103-109. [Div. Zootec. Nutrição Animal.] English summary.

Four Pekin ducks were studied. Sexual maturity was reached at 161 days of age when the average bodyweight was 2615 g. Average yearly egg production was 178 and average egg weight 78.4 g. Maximum bodyweight was reached after 9 months and was, on the average, 2855 g.

The average composition of the whole egg, yolk and white, respectively, was: water 67.4, 48.2, 86.5; protein 14.7, 17.9, 11.8; fat 16.2, 32.3, 0.07 and ash 1.1, 1.6, 0.62 per cent.—P. C. Jowsey.

CARSON, J. R. and JUNNILA, W. A. **Ultraviolet irradiation of the turkey hen.** *Poultry Sci.*, 1953, **32**, 871-873. [Dept. Poultry, Univ. Connecticut, Storrs.]

Groups of 10 Broad Breasted Bronze turkey pullets from 270 to 304 days old were housed in a small-windowed house without outside run. Three lighting regimes were allotted at random to duplicate groups: (1) incandescent light with maximum intensity 6.4 foot-candles, (2) ultraviolet light with 95 per cent. of the lamp energy output in the range 280 to 320 m μ . and maximum light intensity 0.9 foot-candle, (3) incandescent and ultraviolet light (as above) giving a maximum light intensity of 7.9 foot-candles, all measured at bird level. Each group had a 14-hr. light day. Fifty per cent. production in group 2 houses was reached 6 days later than in group 1 and 3 houses. The monthly average egg production of the groups for February, March, April, May and June was 39, 197, 150, 110 and 114; 7, 180, 146, 154, 89; 35, 207, 180, 187 and 150, respectively.—M. J. Head.

RAGAB, M. T. and ASSEM, M. A. **Effect of atmospheric temperature and daylight on egg weight and yield in Fayoumi and Baladi fowls.** *Poultry Sci.*, 1953, **32**, 1021-1027. [Dept. Animal Breeding, Fac. Agric., Fouad I Univ., Cairo.]

The records of 286 Baladi and 245 Fayoumi pullets were studied. Both breeds, indigenous to Egypt and of obscure origin, produce in a year

only 154 small eggs: the average egg weights were 36.6 and 41.0 g., respectively. Egg number and size both decreased as atmospheric temperature increased. Increasing length of daylight increased egg production, but the full effect was not realised, since simultaneously increasing temperature counteracted it. In the first laying year egg size increased gradually up to the eighth or ninth month and then remained constant. There was no positive correlation between egg weight and the number of eggs produced.—T. D. Bell.

OTHER BIRDS

2634

BALDINI, J. T., ROBERTS, R. E. and KIRKPATRICK, C. M. **Low protein rations for the bobwhite quail.** *Poultry Sci.*, 1953, **32**, 945-949. [Dept. Poultry Sci., Agric. Exp. Stat., Purdue Univ., Lafayette, Ind.]

Groups of 35 unsexed day-old quail chicks were used in all the following experiments. In trial 1, groups were given the following percentage supplements to a soya bean and maize ration: (1) 0.30 L-arginine; (2) 0.30 L-lysine; (3) 0.30 L-cysteine; (4) 0.40 DL-threonine; group (5) had no supplement; for a further group (6) the soya bean oilmeal was raised to 60 per cent. and the maize reduced to 34 per cent., giving a total protein content of 28 per cent. compared with 20 per cent. in the basal ration of groups 1 to 5. Groups 2 and 6 weighed on the average 94 and 91 g., respectively, at 6 weeks of age and the other groups 75 g. each.

In trial 2, 10 per cent. wheat bran, rich in

lysine, supplemented soya bean and maize rations containing 20, 24 and 28 per cent. protein. The bran supplement increased growth rate only at the 20 per cent. protein level.

In trial 3, the basal rations for groups 1 to 5 contained maize and soya bean oilmeal in the percentage combinations 40.5 and 25, 40.5 and 30, 50.5 and 20, 40.5 and 25, and 40.5 and 20, with 10 per cent. menhaden fishmeal and 10 per cent. bran. Supplements were given as follows: (1) 5 per cent. maize gluten meal, (4) 5 per cent. dried buttermilk, (5) 10 per cent. dried whey, giving total protein contents of 25, 25, 22, 25 and 22 per cent. Rations 1, 2 and 4 produced the greatest growth, but ration 5, containing only 22 per cent. protein but including 1.4 per cent. lysine, produced better growth than ration 3 with only 1.1 per cent. lysine and the same total protein content.—M. J. Head.

FOOD ECONOMICS AND STATISTICS

2635

PHILLIPS, R. **The fat stock of Anglesey and Caernarvon.** *J. Agric. Sci.*, 1953, **43**, 432-449. [Univ. Coll. Wales, Aberystwyth.]

The trade in fat cattle, calves and sheep through the collecting centres of Anglesey and Caernarvonshire in 1950 was surveyed.

The better climate of Anglesey was closely reflected in the greater weight and better condition of the cattle. The data suggest that many advantages would follow from the zoning of areas for agricultural production. Welsh black cattle were more numerous in both counties, but Herefords were at all times heavier, and steers fattened better than heifers; both these findings are contrary to common opinion.

Sheep are complementary, the hills of Caernarvonshire supplying breeding ewes for the flying flocks of Anglesey. When crossed with rams of heavier breeds they produce fat lambs of almost their own weight in 6 months. Most of the fat stock sales of sheep are of fat ewes, 23, and fat lambs, 73 per cent.—T. D. Bell.

Discussion on organic manures and fertilizers and the production and consumption of food for man and animals. *Proc. Roy. Soc. Med.*, 1953, **46**, 791-798.

Contributions by 4 authorities to the discussion in the Society's Section of Comparative Medicine are reported.

Sir William Ogg, of Rothamsted Experimental Station, said that neither in Britain nor in the U.S. would the annual production of organic manures supply requirements for fertilisers. There was no evidence that erosion was associated with the use of artificial manures or that resulting crops were more prone to disease. In some cases resistance to pests had been shown to be increased in crops fertilised with nitrogen, and survey data indicated that food production in Britain could be increased substantially by the greater use of fertilisers.

Dr. G. C. Ainsworth, of the University College of the South West of England, dealt with soil-plant interactions under natural conditions and under cultivation. Dr. D. P. Cuthbertson, of the Rowett Research Institute, while calling for thorough investigation of any evidence that might be advanced of ill effects arising from the use of artificial fertilisers, emphasised the present lack of such evidence and gave examples of the benefits accruing from their use.

Sir James Scott Watson, of the Ministry of Agriculture, presented the agriculturist's point of view and indicated how rapid had been the advance in knowledge of plant growth over the last century in comparison with the slow accumulation of farming experience over thousands of years. He stressed the need for both prevention of erosion and maintenance of soil structure.

2641

SMITH, H. L. **Report on costs of milk production. 1. Annual report for the year ended 30th September 1952; 63 herds. 2. A five-year review, 1945-46 to 1949-50; 48 identical herds.** *Edinburgh and East Scotland Coll. Agric. (Dept. Econ.) Bull.* No. 38, April 1953, pp. 47.

The herds were mostly Ayrshires with a few Friesians and the yearly size ranged from 6 to 149 cows, with an average of 49 farms ranging in size from a town dairy with 25 acres grassland to an upland farm of 912 acres which included 352 acres of rough grazing. Tuberculin-tested milk was produced by 59 of the herds. Average yield was 767 gal., range from 515 to 991 gal. Annual cost per cow was £85 12s. 11d. and per gal. 26-81d. Profits were £39 2s. per cow or 12-23d. per gal. Feed accounted for 57 per cent. of the total cost, labour 20, miscellaneous 16 and herd maintenance 7. Net costs were 8 per cent. higher than in 1950-1951, though a 4 per cent. increase in milk yield helped to offset this rise. The cost of herd replacement increased by £59 over the previous year to a total of £266 per herd.

The second part of the report shows that the percentage of tuberculin-tested herds increased. Annual yield increased from 626 gal. in 1945-1946 to 730 gal. in 1949-1950, a 16-6 per cent. rise. Net

cost rose from £57 7s. 7d. to £71 4s. 10d. per cow and from 22-02d. to 23-44d. per gal. over the period, and profits from £12 19s. 5d. to £31 18s. per cow or from 4-97d. to 10-49d. per gal. Increased profits were chiefly the result of increased yields and improved managerial efficiency, since these led to lower cost per gal. Increase in herd size led to lower cost per gal. and increase in profit per gal., per head and per year. Over the period the average profits for winter milk were £12 7s. 11d. per cow compared with £10 12s. 10d. for summer milk, or 9-79d. and 6-92d. per gal., respectively.

W. Thomson.

2642

IMPER, A. D. and HAUGHS, M. A. **Report on the production of milk 1951-52. Aberdeen and district milk marketing board area.** *North of Scotland Coll. Agric., Agric. Econ. Dept. Rep.* No. 25, March 1953, pp. 20.

Records of 42 farms where milk production was the main enterprise were studied. The farms, all within the Aberdeen and District Milk Marketing Board area, ranged from 49 to 740 acres, the average size being 169-64 acres with an average rental of £1 4s. 4d. per acre. The average capital employed per cow was £60 18s. 11d., of which £5 19s. 8d. was for dairy equipment. The 42 herds totalled 1803 cows with an average yield of 814-02 gal. All the herds were machine-milked. Only 12 herds were entirely run by hired labour, and 6 by the farmer's family, the remainder by a combination of hired and family labour. The average net cost of keeping a cow for the year was £83 14s. 1d. and the net cost of production per gal. 2s. 1d. Profit per gal. ranged from 6½d. for herds with an average of less than 700 gal. to 1s. 1½d. for herds averaging over 900 gal. The average profit per cow was £36 8s. 1d. and the average profit per gal. was 10½d. Profits were above average in all the herds with a production over 800 gal. per cow per year.—E. L. B. Haskew.

2643

IMPER, A. D. and HAUGHS, M. A. **Report on the production of milk 1951-52. North of Scotland milk marketing board area.** *North of Scotland Coll. Agric., Agric. Econ. Dept. Rep.* No. 26, April 1953, pp. 10.

Completed records of 18 farms within the North of Scotland Milk Marketing Board area were studied. Milk production was the main enterprise, but type and size of herd varied considerably, Ayrshires being the predominating breed. The average capital employed per cow was £60 5s. 6d., of which £7 8s. 2d. was for dairy equipment. The average milk yield per cow was 647-44 gal. Hand milking was still practised on 2 farms. The average net winter cost was £52 2s. 2d. per cow and 3s. 8½d. per gal. and the average net summer cost £32 16s. 9d.

per cow and 1s. 7½d. per gal. The net annual cost of production for graded milk and ungraded milk was 2s. 5¼d. and 3s. 4d. per gal., respectively, the average net cost of production per gal. being 2s. 8¼d. The average net cost of keeping a cow for the year was £85 1s. 6d.—E. L. B. Haskew.

2644

GODFREY, D. **Dairying in Caithness.** *North of Scotland Coll. Agric., Agric. Econ. Dept., Econ. Rep. No. 37, November 1953, pp. 31.*

Over 60 per cent. of the dairy farms in Caithness have less than 30 cows but the density of stocking, owing to greater numbers of sheep, is higher than on the average Scottish dairy farm. Production costs were higher than elsewhere because of medium yield per cow (637 gal.), low yield of oats and high transport costs. The investment per cow was £104, but greater emphasis on winter milk production would increase receipts. Over 60 per cent. of the receipts were from dairying and 12 per cent. from sheep. It is considered that owing to its geographical and climatic conditions Caithness is not specially suited to dairying, and it is postulated that in any future emergency enough milk could be produced nearer the main centres of population, so avoiding the heavy transport costs from Caithness.—W. Thomson.

2645

WITNEY, D. and ROWBOTTOM, J. D. **Dairy labour in the east of Scotland.** *Edinburgh and East Scotland Coll. Agric. (Dept. Econ.) Bull. No. 37, March 1953, pp. 34.*

This study of 64 dairy farms outlines the terms of service for dairy workers, their hours, wages and financial incentives and housing. On all farms the wages were higher than the statutory minima. Bonuses, on a gallonage, clean milk or stock basis, or on a combination of these, were paid on 20 of the 64 farms studied and the advantages and disadvantages of these bonuses are discussed.—W. Thomson.

BARKER, A. S. and HADDEN, M. A. **Self-sufficiency in milk production. A case study.** *Imperial Chemical Industries, Ltd., Agric. Development Dept. Bull. No. 4, August 1953, pp. 27.*

This is a description of the development and management of a dairy farm in Northern Ireland which is entirely self-sufficient. Only grazing and grass silage are now used for the maintenance of the herd and the production of milk. The figures presented show the increased production per acre and profit per cow over 5 years from 1948 to 1953. Pastures are kept in good condition by liberal fertilising. In 1951 it was found possible and

profitable to stop the purchase of concentrates as unnecessary.—T. D. Bell.

2647

KOIVISTO, E. Tutkimuksia Suomen kulutusmaito-markkinoista erikoisesti kulutusmaidon hinnanmuodostumisen kannalta katsottuna. [The market for liquid milk in Finland, with special reference to the market price.] *Acta agral. fenn.*, 1953, 82, pp. 161. German summary.

The object of the investigation was to clarify the problem of marketing fresh milk in Finland. In particular the effects of the second world war and the conditions in the subsequent years on supply of milk to the cities, region of production, means of transport, and use to which the milk was put on reaching the cities, *i.e.*, the relative proportions of the milk sold fresh and going to creameries for processing, were studied. For this purpose the data available for Helsinki were used.

A statistical examination was made of all the data. It covered seasonal variations in sale price of the fresh milk, its relation to cost of production, the effect of price on quantity purchased and the relation between demand and the income of the purchaser. It was found that milk consumption depended on two independent variables, the income and the numbers in the household.

The milk supply to Helsinki was at its lowest in 1945, amounting then to only 44 per cent. of that in 1938. After 1945 it rose quickly and in 1951 had reached 120.4 million litres, exceeding the figure for 1938 by 11.2 million litres. Yet the supply per head of the population was only 0.88 litre daily as compared with 1.08 in 1938. Supplies of butter and cheese as supplements, when calculated as milk equivalents, were 26.6 per cent. of total supplies in 1947, but had fallen to 10.8 per cent. in 1950 and risen again to 24.3 per cent. in 1951. Reasons for these variations are discussed. Though there were marked seasonal variations in supplies of fresh milk reaching Helsinki, these were smoothed out to a considerable extent by these supplies of milk supplements.

A weekly variation in milk sales was noted. Taking the average sales on Wednesdays as 100, those on Saturdays were 148 to 170 and on other days 104 to 107.

Owing to alterations in transport conditions and the increase in motor transport, supplies of fresh milk as well as of butter and cheese have been reaching Helsinki from more remote provinces and at the present time only 5.6 per cent. of the milk is reaching the city by rail.

All the changes in milk supply and demands and the conditions affecting them are examined on the basis of elasticity coefficients. (From summary.)

JONES, W. A. C. Cattle costs—winter 1952-53. *North of Scotland Coll. Agric. Econ. Rep.* No. 36, October 1953, pp. 17.

A total of 886 cattle made up of 24 groups of Aberdeen-Angus or its crosses, 2 groups of Short-horn crosses and 6 groups of other crosses were costed for the winter feeding period of around 26 weeks. Three groups were court-fed and the remainder stall-fed. The average cost was £18 4s. Eighty-five per cent. of the cattle were graded for slaughter as super-specials and the average profit was £9 11s. 6d. compared with £10 7s. for 1951-52 and £7 0s. 6d. for 1950-51, but returns varied from a loss of 6s. per head for one lot to a profit of £15 for 4 lots. Homegrown feeds accounted for 84.5 per cent. and purchased feeds for 4.6 per cent. of the total cost of 16s. 2d. weekly. There was an upward trend in both buying and selling prices.

Fifteen groups totalling 304 store cattle, mostly of Aberdeen-Angus origin, were costed throughout the winter period of 26 weeks. All were court-fed, generally on turnips and oat straw, with grass silage for 2 lots. Total costs ranged from £11 to £17 per head with an average of £14 15s. 6d. or 11s. 2d. weekly.

The wintering of 712 weaned calves on 34 different farms was studied for the 26-week period. On 12 Caithness farms the total cost per head was £15 15s., on 10 others outside Caithness but receiving the hill cattle subsidy £14 10s. 5d., on 7 in lowland areas £11 1s. 9d. and on 5 farms with calves from outwintered herds £10 16s. 5d. Homegrown feeds accounted for from 76 to 82 per cent. and purchased feeds for from 5.7 to 9 per cent. of the total cost. Costs are greatly affected by variations in the yield of oats and turnips. On 9 groups sold at the end of the period there was an average loss of £10 6s. 7d., excluding the subsidy of £15.—W. Thomson.

Vol. 24, No. 2

2652

CAMBRIDGE UNIVERSITY SCHOOL OF AGRICULTURE, FARM ECONOMICS BRANCH. Profits in pig production. *Farmers' Bull.* No. 14, February 1953, pp. 23 + iii.

In the 47 enterprises recorded, individual farmers had up to 100 breeding sows or 300 fattening pigs. For every £100 gross output, average costs were £84, leaving a profit of £16. The best farmers made profits up to 30 per cent. of gross output but the worst made losses of nearly 10 per cent. Feed accounted for 84½ per cent. and labour for 9½ per cent. of all costs. The cost of producing a weaned pig was £2 10s. on the best farms, but the average was £4 10s.; costs could be greatly reduced by an increase in numbers weaned per sow per year. For fattening pigs the average meal requirement was 4.75 lb. per lb. live-weight increase, the best being 3.64 lb. Where potatoes or fodder beets were used the requirement was on the average 3.75 lb. meal equivalent. Grading and market prospects are discussed in the light of this survey. The effects of feed prices on costs of production and on ruling bacon prices are also discussed.—W. Thomson.

2653

ENGELMAN, G., DOWELL, A. A. and OLSON, R. E. Relative accuracy of pricing butcher hogs on foot and by carcass weight and grade. *Minnesota Agric. Exp. Stat. Tech. Bull.* No. 208, June 1953, pp. 48. [Dept. Agric. Econ.]

In the U.S. pigs for slaughter are usually sold on a liveweight basis. Thus animals of good carcass quality are generally not priced highly enough and farmers are overpaid for others of inferior quality. The object of the investigation reported was to estimate the relative accuracy in relation to carcass cut-out value of payment on the basis of liveweight, liveweight plus estimated carcass yield and estimated carcass grade, or carcass weight and grades.

The variability of cut-out values above and below the prices paid on the basis of the average weight of the lot of pigs was the pricing error. This was reduced by 16 per cent. when each pig was weighed and paid for individually and by 15 per cent. when estimates of carcass yield and carcass grade were made for each pig. In making these estimates, however, the buyer overgraded all pigs. A correction was made to allow for his inexperience and then this method reduced the pricing error by 38 per cent. A live grading method which gives no consideration to carcass yield was correct for 56 per cent. of the pigs and the pricing error was reduced by 43 per cent. When pigs were priced by carcass weight and grade the pricing error was reduced by 82 per cent. This

proved to be the most accurate price assessment studied.

The implications of a change-over to payment on a carcass weight and grade system are fully discussed. References are made to the bargaining for, and selling of pigs for slaughter, packing house reorganisation, the identification of bruised and diseased pigs and the probable acceptability, benefits, and difficulties of the change-over to producers, packers and consumers.—I. Lucas.

2654

HENNING, G. F. and EVANS, M. B. **Market hogs can be accurately graded.** *Ohio Agric. Exp. Stat. Res. Bull.* No. 728, June 1953, pp. 71. [Wooster, Ohio.]

This report is in 2 sections. The purpose of Section 1 was to investigate which carcass measurements were correlated with the percentage yields of the 4 trimmed lean cuts (hams, loins, picnics and butts), to estimate the shrinkage of carcasses after chilling and to develop carcass grades applicable to live pigs but based on carcass measurements. The purpose of Section 2 was to test the applicability in practice of the standards developed in Section 1.

The results from Section 1 indicated that most of the variation in yield of lean cuts could be correlated with variations in mean backfat thickness, length of carcass, length of hind leg and weight of carcass. Grades for live pigs were suggested which were based upon estimates by the grades of these 4 variables. The shrinkage data showed that after 24 hr. in the chill rooms light or lean carcasses shrank more than heavy or fat carcasses. If carcasses were kept in the chill rooms for 48 instead of 24 hr. the shrinkage increased by a further one-half per cent.

Section 2 reported wide variation in ability of graders to assess carcass quality accurately from live pigs. The best grader judged the quality of from 40.5 to 64.4 per cent. of the pigs in each lot accurately. Comparison of live grading with carcass grading revealed a slightly better accuracy for carcass grading. It was concluded that both live grading and carcass grading methods are

worthy of consideration in improving the system of marketing pigs in the U.S.—I. Lucas.

DIET IN ETIOLOGY OF DISEASE

GENERAL

2660

ENGLERT, H. K., BAUER, H. and KUMMER, H. **Über die Fischmehlkrankheit des Schweines. [Fishmeal disease of pigs.]** *Arch. Tierernährung*, 1953, 3, 195–222. [Tierhyg. Inst., Freiburg i. Br.]

This is an account of co-operative work undertaken as the result of an outbreak of fishmeal

disease among fattening pigs from different stocks under test at the State research station, which was demonstrated to be due to feeding a particular fishmeal. After a survey of the literature, the progress of the disease and the clinical, pathological and histological findings are described. Eczema and hyperkeratosis of the outer skin and particularly of the mucous membrane of the tongue, not previously recorded, were prominent. A thorough

N.A. and B., April 1954

examination of the suspected fishmeal gave no clue to the cause of the disease. Vitamin B deficiency or any binding of the complex was excluded. Possible deficiency of vitamins A or C was not investigated.

In view of the economic importance of fishmeal in pig feeding it is considered that further attention should be given to the qualitative and quantitative methods used in the examination of fish-meals, in order that samples of poor quality or liable to contain products of decomposition of the raw material may be detected.—W. Godden.

2661

MASON, M. M. and GILVARG, C. **Bracken fern poisoning in Massachusetts.** *Vet. Med.*, 1953, **48**, 508-509. [Worcester, Mass.]

In a herd of cattle grazing on pasture, 4 of 10 calves developed chronic bloat. No cause for the condition could be found; the animals were provided with good clean pasture and overgrazing was avoided, and they gradually recovered without treatment.

Less than a month later, a cow from the same herd developed a temperature of 108° F., with profuse diarrhoea, and died within 24 hr. Autopsy revealed areas of subcutaneous haemorrhage and numerous petechial haemorrhagic areas on the surface and in the substance of lungs, heart, kidneys, gallbladder and urinary bladder, while the entire colon was filled with masses of clotted blood. Although no direct evidence was found to suggest that abnormal fodder had been ingested, there was much bracken in the district and a tentative diagnosis of bracken poisoning was made.

At this stage the entire herd was taken off pasture and fed on good hay and oats, but within 6 weeks 4 other adult animals developed similar signs and died.

The lack of any specific means for diagnosis and therapy in bracken poisoning is pointed out, and, no matter how intensely bracken may be fed, a long period is required to produce any sign, but deaths may continue for some time after animals are taken off bracken. It is suggested that bracken feeding may cause the production of some substance which is stored until a critical level is reached, when it precipitates fatal haemorrhagic disease.

BLAXTER, K. L. and WOOD, W. A. **Some observations on the biochemical and physiological events associated with diarrhoea in calves.** *Vet. Rec.*, 1953, **65**, 889-892. [Hannah Dairy Res. Inst., Kirkhill, Ayr.]

Information obtained in the course of a series of metabolic experiments with normal and scouring calves is summarised. Normal calves given milk

Vol. 24, No. 2

or milk substitutes sometimes did not defecate for several days, but over long periods the average weight of faeces produced daily was 50 to 60 g., of which 15 to 20 g. was dry matter. In scouring calves faecal loss was much increased, averaging in severe cases 20 times, but sometimes as much as 40 times, the normal. In a series of 160 analyses of faeces from 8 calves, it was found that this increase was mainly accounted for by water, and indeed the percentage of dry matter in the faeces could be used as a measure of the intensity of the diarrhoea; but dry matter also was increased on the average by 7½ times. Apparent digestibility fell, sometimes to as low as 40 per cent., and fat-soluble vitamins were lost in greater amounts.

Free fatty acid excretion was enormously increased, on the average about 26 times; its increase was of the same order as that of the coliform count, indicating that the unabsorbed material had undergone bacterial fermentation. Steam-volatile fatty acids and "total fat" were increased about 6 to 7 times, and soaps 4 to 5 times. Excretion of purine N, probably of bacterial origin, rose from nil in normal calves to 270 mg. daily in scouring calves, and faecal pH fell from 6.8 to 6.0. Passage of feed through the digestive tract took 48 hr. in normal calves, but only 6 hr. in scouring calves.

In scouring calves, the increase in Ca, Mg and P excretion was of the same order as that of soaps, but in severe cases Na and K loss was about 11 times greater than normal, and was directly correlated with water content. K loss was particularly marked in animals losing weight. Despite these heavy faecal Na and K losses, urinary Na and K declined only slightly.

It is suggested from all this evidence that scouring arises from a primary disturbance high in the intestinal tract, which causes the formation lower down of a substrate of undigested food very suitable for massive bacterial fermentation. This leads to an increase in the number of small molecules and hence to increased osmotic pressure within the gut lumen, which in turn causes water and electrolyte infiltration. Acid irritation of the mucosa, increased motor activity, loss of the protective mucus from the intestinal wall and partial invasion of the gut by bacteria possibly contribute in the later stages. The part played by bacteria in the etiology of scouring may therefore be secondary in its inception, but not necessarily in its ultimate outcome.

As a cause of the primary digestive disturbance, the authors emphasise the importance of rennet clot formation and the influence on this of Ca ions.

DEFICIENCY DISEASES

2668

HARVEY, J. M. and SUTHERLAND, A. K. **Parenteral copper therapy in ruminants.** *Austral. Vet. J.*, 1953, **29**, 261-268. [Dept. Agric. Stock, Brisbane, Queensland.]

Because previously accepted methods of giving copper all have disadvantages, a parenteral method, suitable for use in the field, was sought. Intravenous injection was not considered, as it would be impracticable for stock owners.

Copper-deficient sheep and cattle were used to test 13 Cu compounds given by subcutaneous injection. The percentage retention and degree of storage of Cu from each inoculum was estimated from auto-controlled balance studies or from pre- and post-treatment liver biopsies, or by both methods. Blood Cu values, estimated both before and at intervals after Cu administration, were used

as guides to uptake and toxicity. The inocula were designed to contain 50 mg. Cu for sheep and 200 mg. Cu for cattle.

Ten readily ionisable Cu compounds administered subcutaneously to sheep all produced damage at the site of inoculation, but with copper oxine (8-hydroxyquinoline), copper versenate (ethylenediamine tetra-acetate) and copper glycinate (aminoacetate) cuticular lesions were very slight. The oxine, however, was so insoluble that it was not metabolised, and the versenate proved extremely toxic. The glycinate was satisfactory in doses of 50 mg. Cu, but toxic in doses of 100 mg. Cu. Intramuscular injection of copper sulphate was satisfactory provided the whole inoculum was lodged in a muscle mass.

With cattle, 200 mg. Cu as the sulphate injected intramuscularly produced no ill effect in 3 bullocks, but caused lameness, inappetence and reduced milk production in 6 dairy cows for 48 hr. Their blood Cu values were raised and maintained for 5 months.—W. A. Greig.

WALSH, T., NEENAN, M. and O'MOORE, L. B. **The importance of molybdenum in relation to some cropping and livestock problems under Irish conditions.** *J. Dept. Agric., Éire*, 1951-52, **48**, 32-43. [Soil Lab., Dept. Agric.]

This is a preliminary report. A condition in livestock, similar to that described elsewhere as conditioned copper deficiency, is relatively widespread. It responds to treatment with Cu, but pastures are not low in Cu. The Mo content of affected pastures ranges from 5 to 25 p.p.m. Total soil Mo values are normal, but the percentage of total Mo which is readily available is high. The condition occurs on both mineral and organic soils. In general affected soils are within the pH range 6.8 to 7.8. Both lime and phosphates, especially monocalcium phosphate, increase the Mo content of herbage. High Ca:P ratios in herbage are associated with the condition in livestock. Clovers have a higher uptake of Mo from soil than grasses and weeds.

It is noted also that soil from selenium-toxic areas is high in available Mo.

Mo deficiency in crops is another aspect of the Mo problem in Ireland. This is briefly considered. Fertilising with copper sulphate has an adverse effect on Mo-deficient crops; liming or treatment with Mo is beneficial.—F. C. Aitken.

GRASHUIS, J., LEHR, J. J., BEUVERY, L. L. E. and BEUVERY-ASMAN, A. **Mangaandeficiëntie bij rundvee. [Manganese deficiency in cattle.]** *Inst. Moderne Veevoeding "De Schothorst"*, 1953, pp. 16. English summary.

N.A. and B., April 1954

A syndrome of poor growth and bone deformities, with low fertility, described by Bentley and Phillips (Abst. 2818, Vol. 21) in heifers and attributed to deficiency of Mn, is thought to be common on Netherlands farms where the pH of the soil is high. The quality of the pasture is otherwise good and a top-dressing of Mn removes all trouble. Details are given of a series of soil and pasture analyses and analyses of organs from 2 heifers, of which one showed characteristic abnormalities, from a typical farm.—I. Leitch.

RODRÍGUEZ MORENO, F. F. Modificación del tiroideo en la profilaxis del bocio endémico por la sal yodada. [**Changes in the thyroid in prophylaxis of endemic goitre with iodised salt.**] *Rev. clín. española*, 1953, **50**, 270-285. [Hosp. Cantonal, Aarau, Switzerland.] English, German and French summaries.

To assess the prophylactic effect of iodised salt against endemic goitre in the Canton of Thurgau in Switzerland, anatomical studies were made of thyroids of 182 calves from 3 districts differing in intake of I. In one district 60 per cent. of the salt consumed contained 5 mg. KI per kg.; in the other districts all the salt consumed had either 5 or 20 mg. KI per kg. With increasing amounts of iodised salt there was a reduction in the absolute and relative weights of the thyroids. Histological examinations indicated a parallel between weight and activity, inactivity being observed only when the weights of the glands were less than 0.6 g. per kg. bodyweight. Increasing amounts of I caused a reduction in the size of the follicles, made them more homogeneous and increased the size of the nuclei. Variations in the appearance of the nuclei also were observed, and their significance is discussed.—M. B. Richards.

HARVEY, J. M. **Further studies of fluorosis in Merino sheep.** *Queensland J. Agric. Sci.*, 1953, **10**, 109-124. [Biochem. Sect., Chem. Lab., Div. Plant Indust.]

Six sheep, which in a previous experiment (Abst. 1408, Vol. 24) had been pen-fed and given drinking water containing 10 or 5 p.p.m. F, were given for 30 months drinking water containing not more than 0.2 p.p.m. F. During this time they had access to pasture and alfalfa hay. The incisor teeth were examined monthly and after autopsy at 57 months of age X-ray studies were made of femur, tibia and mandible and F was estimated in muscle, kidney, bones and teeth.

Comparison of the results with those obtained at 37 months from similar sheep immediately after exposure to F indicated that the dental lesions of fluorosis are permanent and that the effects of erosion and wear are enhanced by age despite later protection from F. The bone defects previously reported are apparently not permanent.

LEE, H. J. and KUCHEL, R. E. **Phalaris tuberosa and phalaris staggers in sheep and cattle. Investigational work on phalaris staggers in sheep.** *J. Dept. Agric. S. Austral.*, 1953, **56**, 493-495 (with discussion 495-498). [Div. Biochem., C.S.I.R.O.]

For previous article see Title 1414, Vol. 24.

Sheep were kept on 3 pastures: subterranean clover, 22 ewes, 11 receiving 7 mg. Co per head weekly; alfalfa, 22 ewes, 11 receiving the Co supplement; mixed pasture including subterranean clover, alfalfa and *Phalaris tuberosa*, 25 ewes, 10 receiving the Co supplement. No ewe developed staggers on the first 2 pastures; 11 of the unsupplemented ewes on the mixed pasture developed staggers, but none of the ewes given Co.

The protective effect of frequent doses of Co was confirmed in a second series of tests. A massive but infrequent dose, 280 mg. Co per sheep at intervals of 4 weeks, did not prevent staggers.

It is suggested that the Co exerts its protective effect by increasing production of vitamin B₁₂ in the animal body and allows the animal to destroy more rapidly the toxic substances present in *Phalaris*. The work continues.—P. C. Jowsey.

2676

WHITEHEAD, E. I. and MOXON, A. L. **Nitrate poisoning.** *S. Dakota Agric. Exp. Stat. Bull.* No. 424, June 1952, pp. 24.

Nitrate in feedingstuffs is reduced to nitrite by the micro-organisms of the gastro-intestinal tract of animals. The nitrite converts the haemoglobin of the blood to methaemoglobin and if the change is pronounced enough the animals may die of asphyxiation.

Oat, barley, wheat or rye hay, maize and sorghum fodder all may contain toxic amounts of nitrate when environmental conditions have been unfavourable to normal plant growth. Drought is particularly conducive to the accumulation of nitrate. Young plants often contain large amounts of nitrate, which decreases as the plants mature. Herbicide sprays may also increase nitrate in leaves. Beet leaves inadvertently sprayed with 2, 4-D contained on the average 4.50 per cent. KNO_3 on a dry matter basis, unsprayed leaves only 0.22 per cent. Other conditions affecting nitrate accumulation in plants are the nitrate content of the soil and the presence or absence of certain trace elements essential to enzyme function.

Nitrate poisoning in livestock has been successfully treated by intravenous injections of a solution of methylene blue or of thionine. The latter is itself toxic above a certain level.

Nitrate poisoning in infants was traced to well-water which contained up to 801 p.p.m. nitrate N. Water containing more than 10 p.p.m. nitrate N is considered unsafe for infant feeding. Treatment is by injection of methylene blue or large doses of ascorbic acid given intramuscularly or subcutaneously.—P. C. Jowsey.

2688

VOGL, A. **Diuretic therapy.** Baillière, Tindall and Cox, London, 1953, pp. xiii + 248. Price 38s. 6d.

The emphasis in this book is not nutritional, its sub-title being "The pharmacology of diuretic agents and the clinical management of the edematous patient". In that part which is devoted to practical treatment the different types of diets for restricting salt intake are described, and as the book has its origin in the United States of America

the menus are designed accordingly. Both the subject and its treatment may limit interest in the book to medical practitioners but its text and the very full bibliography contain many references of value to physiologists interested in the metabolism of water and electrolytes.—D. Harvey.

2689

COOPER, M. M. **Beef production.** T. Nelson and Sons, Ltd., London, 1953, pp. x + 234. Price 12s. 6d.

In view of the fact that the recently published February Price Review seems to indicate a swing of the pendulum in favour of beef production—long the Cinderella of British agriculture—this is a very timely book.

The first two chapters introduce the subject and deal with the history of beef cattle; there follow eight chapters covering the science and practice of genetics, breeding and nutrition. Three chapters deal with different types of beef enterprise, and the last chapter, "Economic Considerations", summarises the problems encountered and offers solutions. In general, the British beef industry, past, present and future, is discussed thoroughly in all its aspects.—E. L. B. Haskew.

2690

BOURNE, G. H. and KIDDER, G. W. (Eds.) **Biochemistry and physiology of nutrition. Volumes 1 and 2.** Academic Press, Inc., New York, 1953, pp. xiii + 569; xi + 641. Prices \$13 and \$15.

Their undertaking "to gather into one work the most salient segments of the vast amount of research dealing with the field of nutrition" has been achieved by the editors in the 23 chapters of this treatise written by 28 authors. It is a product of Anglo-American co-operation the measure of which is indicated by 11 chapters being from American, 1 from an Australian and 11 from British addresses. The extent of the subjects discussed may be judged from the list of nearly 5500 references to publications and from the size of the double-volume indexes, 86 pages for subjects and 69 for authors' names.

The range of subjects is wide. The history of the early development of the science is by the late E. P. Cathcart who, by his dietary surveys, pioneered in the application of the subject of this treatise to human welfare and whose recent death has meant a loss to physiological science in Britain. The history of vitamins is dealt with by Harris.

Chapters on water and electrolytes by Zwemer, carbohydrates by Sourkes, lipids by Frazer, iron by Kirkpatrick and calcium and phosphorus by Kirkpatrick and Robertson deal specifically with the metabolism of these constituents of foods; others on amino-acids by Meister, vitamin B

complex by Kon and Porter, vitamin C by Lloyd and Sinclair, fat-soluble vitamins by Moore, and trace elements by Underwood are wider in their treatment and are concerned also with the chemistry of these nutrients. Chapters on more specialised branches of biochemistry and physiology are by Borsook and Deasy on the biosynthesis of proteins, by Cuthbertson and Phillipson on the microbiology of digestion and by Jukes on vitamins and haematopoiesis. Considerable stress is laid on the subject of changes occurring in tissues in the chapters on energetics and metabolic function by Kennedy, on hydrolytic and phosphorolytic enzymes by Yudkin, on respiratory enzymes by Horecker and Kornberg and on co-enzymes by

Novelli and Soodak. The editors' own contributions are in different fields, Bourne's chapters on the localisation of enzymes and vitamins and on the structural changes in vitamin deficiency being largely histological and Kidder's on the nutrition of invertebrate animals being the subject in which probably most remains to be done. A final chapter by Goldsmith summarises the application of the science of nutrition to man.

The cost in time and thought to the contributors and editors of this authenticated handbook of nutrition must have been considerable; the cost in money to purchasers will also be high. Those wishing to benefit from the one may be deterred from doing so by the other.—D. Harvey.

8. FOOD AND AGRICULTURE ORGANIZATION (AND OTHER ORGANIZATIONS) OF THE UNITED NATIONS

Report of the Council of FAO. Eighteenth Session, 18–20 November 1953; Nineteenth Session, 12 December 1953. Rome, Italy, January 1954, pp. 40.

Monthly Bulletin of Agricultural Economics and Statistics. Vol. 2, No. 12, December 1953, pp. 48. Price \$0.50, p. 1. Some aspects of interchangeability among fats and oils. Vol. 3, No. 1, January 1954, pp. 32. Price \$0.50; No. 2, February 1954, pp. 48. Price \$0.50.

Grain exports by source and destination, July 1952–June 1953. Rome, Italy, November 1953, pp. 20. Price \$0.25.

Commodity Reports. Rice No. 4. Rome, Italy, December 1953, pp. 33. Price \$0.25.

Nutritional Studies No. 10. School feeding. Its contribution to child nutrition. Rome, Italy, November 1953, pp. v + 129. Price \$1.00.

The history of school feeding from its charitable beginnings to its present position as a social responsibility is traced and brief summaries are given of the many experiments and schemes which have been put into operation all over the world. Most of these have been based on milk but useful data have been collected for other supplementary foods in areas where milk supplies were inadequate. The administration of such schemes is described and their educational and social aspects are considered in the light of arguments both for and against them. The operation of school meals services requires quantities of food which may range from the produce of a school garden to surplus supplies the accumulation of which may have an effect on farm prices. The disposal of such stocks in this most profitable manner may not only be of national importance but may, as the work of UNRRA and UNICEF has shown, have international implications. A final chapter deals with the extension of the work to the more vulnerable pre-school child. There are appendices which

describe the work geographically, give notes on the use of dried milk and summarise the methods of evaluating the results obtained from supplementary feeding.

FAO Nutrition Meetings Report Series No. 6. Report of the Nutrition Committee for South and East Asia. Third meeting, Bandung, Indonesia, 23–30 June, 1953. Rome, Italy, November 1953, pp. iii + 38. Price \$0.40.

Progress made since the second meeting of the committee (see p. 516, Vol. 20) is reported. In Indonesia where most of the rice used is home pounded beriberi is not a problem but in Thailand where polishing has been introduced the disease has appeared. The consumption of under-milled rice is being encouraged throughout the area and care in washing and cooking of the cereal is advised. Improvement of rice diets is urged by the use of fish in India and Japan, of pulses and groundnuts in the Philippines and of silk worm chrysalis, a food local to North Viet Nam.

The malnutrition of mothers, infants and children with regard to protein is considered in detail. The differences between severe kwashiorkor as described by the Joint Expert Committee on Nutrition (see next abstract) and protein deficiency disease in children in South and East Asia are described and reference is made to the important part which the nutrition of the mother may play in its causation. The long-term effects on the health of the adult populations are not fully understood and suggestions for field, laboratory and chemical research are advanced. The parts which food production, distribution and processing may play in its prevention are described.

Endemic goitre occurs in India, Indochina and Thailand and has a high incidence in parts of Indonesia. The use of iodates in prophylaxis is recommended. The importance of calcium in human nutrition is also emphasised but, until more information becomes available, no recommendations are put forward for allowances; it is, however, suggested that the Ca content of local diets should be increased. Brief reference is made to deficiencies of vitamin A and riboflavin in the diets of the populations.

N.A. and R., April 1954

The activities in the various territories for education in nutrition and the training of workers for nutrition programmes in communities and schools are dealt with in full.

World Health Organization. Technical Report Series No. 72. Joint FAO/WHO Expert Committee on Nutrition. Third Report. Session held at Fajara, Gambia, 28 Nov.-3 Dec. 1952. Geneva, December 1953. Price \$0.20. Issued also as FAO Nutrition Meetings Reports Series No. 7.

This report is concerned with deficiency of protein in the diet of infants and children, a subject the further study of which was recommended at the second session (see p. 1016, Vol. 21). It is considered from a number of aspects: its cause, namely food supply, population growth and economic status and social customs; its extent both in incidence and in long-term effects; its treatment which is largely dietetic; and its prevention by changes in the diet of the population as a whole or by the special feeding of pregnant and lactating women and infants.

But the kernel of the problem is reached only when the practical application of programmes to improve nutrition is considered. In this connection emphasis is laid on the need for local surveys to discover what the people know already, to gain their confidence, and to instil in them a feeling that their problems are being approached sympathetically. Integration with the local beliefs and customs of plans for improvement will do much to encourage their adoption. A number of lines along which field, clinical and laboratory researches might proceed are indicated.

The report ends with appendices giving a description of severe kwashiorkor, a list of no fewer than 38 names which have been applied to the syndrome and a general

note on food production and the extension methods likely to help bridge the gap between science and practice.

Development Paper No. 38. Manual of field studies on the heat tolerance of domestic animals. Rome, Italy, December 1953, pp. x + 161. Price \$2.00.

The origin of the plans and techniques described in this manual may be traced to recommendations made in the earlier Development Papers Nos. 6, 8 and 33. In the meantime the methods proposed have been examined by the author, Dr. D. H. K. Lee, and by a panel of experienced investigators. Two chapters deal with specific techniques for the study of environmental conditions and four with various aspects of the study of animal reactions. It is hoped that the manual, which is in no way intended to be a final statement of methods to be employed, will have the effect of encouraging investigators to make their observations according to an agreed plan and it is only with this systematic collection of data that it is concerned. The much more complex subjects of the integration and interpretation of findings are not considered.

If the aim of FAO in arranging for its compilation is to be attained the manual will need to be in the hands of all who are interested in the problems of the animal breeder and producer in the tropics.

Material on Home Economics and its Teaching. Rome, Italy, 1953. Mimeographed, pp. 152. Price \$0.50.

The material supplied by member governments in response to a request by FAO for information on Home Economics programmes, methods of evaluation of teaching and on teaching aids has been analysed and classified. The tables give title, date, form, author and language of the publications and the address from which copies of each may be obtained.

9. DEPARTMENTAL AND OTHER REPORTS

AUSTRALIA.

Annual Report of the Department of Agriculture and Stock, Queensland, for the Year 1952-53. Pp. 118.

Copper deficiency and steely wool.
Hand-feeding of sheep in drought time.
Urea feeding on protein-deficient pastures.
Adaptation of merino rams to the tropics.
Plane of nutrition and milk yield of ewes.
Top-dressing of copper-deficient areas.
Antibiotics for poultry.
Value of condensed whey solubles for poultry.
Egg production, feed utilisation and flesh qualities of White Leghorn × Australorp cross.

NEW ZEALAND.

Animal Research Division of the New Zealand Department of Agriculture. Annual Report for the Year 1952-53. Pp. 31.

Rickets-producing factor (carotene) in green feed.
Rate of stocking in relation to fat-lamb production.

Vol. 24, No. 2.

Rotational grazing *vs.* set-stocking of ewes and lambs.
Technique of measurement of intake of grazing sheep.
Fertility in dairy bulls. Effect of nutrition.
Implications of nutrition levels on dairy cattle improvement.
Influence of climate on performance of dairy cattle.
Dairy cow nutrition. Lifetime project.
Effect of thyroxine on milk production.
Performance of identical twins previously subjected to differential treatment.
Grazing behaviour in relation to bloat.
Effect of plane of nutrition on milk production in the sow.
Cobalt deficiency. Therapeutic trials with vitamin B₁₂ (lamb).
Molybdenum excess and copper deficiency (cattle).

SOUTHERN RHODESIA.

Annual Report of the Nutritional Council for 1953. Pp. 7.

Commercial production of tempe (fermented soya bean).
Production of tortilla (Mexican maize bread).
Fortification of maize meal with calcium, nicotinic acid and riboflavin.

Iodine deficiency and use of iodised salt.
 Fluorosis and the addition of fluorine to drinking water.
 Investigation of kwashiorkor.
 Investigation of native plant relishes.

FEDERATION OF MALAYA.

Annual Report of the Institute for Medical Research for the Year 1952. Pp. 107.

Methods of parboiling rice and effect on calcium, iron and phytic acid content.
 Effect of soil, cultural conditions and variety on nutrients of rice.
 Vitamin B₁ and riboflavin in mung bean and changes during germination.
 Haemoglobin survey of rural communities.
 Liver damage of nutritional origin.
 Vitamin B₁ in human milk.
 Calcium and phosphorus in blood from buffaloes grazing suspected deficiency areas.

UNITED STATES OF AMERICA.

Mississippi Agricultural Experiment Station. Sixty-sixth Annual Report for the Fiscal Year ending June 30, 1953. Pp. 110.

Salt as regulator of protein intake of beef cattle.
 Shrimp meal as feed for pigs.
 Effect of concentrate feed intake on forage consumption of growing pigs.
 Inactivation of gossypol in cottonseed meal by ferrous sulphate.
 Enrichment of whole ground maize meal with iron, vitamin B₁, riboflavin and nicotinic acid.

United States Department of Agriculture. Report of the Chief of the Bureau of Animal Industry 1953. Pp. 123.

Estimating the composition of live meat animals.
 Hormones and vitamins unsatisfactory for inducing pregnancy in goats.
 Effect of high-fat ration on milk and butterfat production in goats.

Carotene utilisation by sheep; effect of level in diet, pelleted or unpelleted feed and admixture of fat.
 Utilisation of inorganic sulphur by sheep shown by radio-isotopes.
 Effect of temperature of processing on nutritive value of cottonseed meal.
 High phytin content of cottonseed meal and effect on metabolism of calcium, phosphorus and vitamin D.
 Pantothenic acid requirement of the baby pig.
 Addition of aureomycin-vitamin B₁₂ supplement to a low-protein ration for sows improves baby pig survival.
 Deposition of vitamin B₁₂ in hen's eggs.
 Comparison of chick assay and microbiological assay for measuring vitamin B₁₂ activity.
 Retention of vitamin B₁₂ by chickens.
 Alfalfa saponin and inhibition of growth of chickens.
 Thyroprotein and fat in laying rations.
 Effect of antibiotics and vitamin B₁₂ on enteritis in rabbits.
 Fibre and physical form of roughage not a factor in causing enteritis in rabbits.

Report of the Chief of the Bureau of Dairy Industry 1953. Pp. 26.

Adjustment factors for converting milk production records to same basis.
 Feeding alfalfa pellets to cows on poor-quality hay.
 Heifers on alfalfa hay make better growth than on alfalfa silage.
 Differences in nutritive value of alfalfa hay and alfalfa silage not associated with rumen bacteria.
 Amount and digestibility of forage consumed by grazing animals estimated by internal and external indicator ratios.
 Sodium metabisulphite as silage conditioner.
 New lactometric method for estimating non-fat solids in milk.

Report of the Chief of the Bureau of Human Nutrition and Home Economics 1953. Pp. 14.

Levels of living on farms.
 Diets of American women.
 Food surveys in families in farming areas in the South.
 Fatty acid requirements of children.
 Amino-acid requirements of young women.
 Amino-acids in vegetable products.
 Effect of antibiotics on flavour of turkey flesh.

INTRODUCTION

IN a world in which the arable land areas have been almost fully explored, the food production capacities of the seas with their three dimensions have, until recently, attracted singularly little attention. Perhaps this is understandable because, in the past, populations had not saturated the habitable areas, and emigration relieved population pressures to an extent which today is growing more and more difficult to achieve. The time has come when mere multiplication of mouths has forced attention on to this last of the unexplored possibilities.

This time would have come, though much more slowly, had it not been for the impact of two great wars and especially of the last one. It has, of course, long been recognised that the low level of production and consumption in the underdeveloped areas and the great disparity in this respect between them and the more highly developed areas constitute the most serious aspect of the food problem. And it had long been known that the rate of human multiplication and survival was increasing. But the effect of the second world war was to aggravate and intensify these problems. Territories were laid waste, livestock was killed, stores and processing facilities were destroyed and many of the most productive areas of the sea were almost completely closed to fishing.

The impact of this produced, in many places, widespread shortage, and in some places downright starvation. Though this decreased survival, it did not reduce birth rates, and populations continued

to grow as if the resilience of the human animal responded to the challenge of impending death.

All this brought the food problem nearer to the point where man could no longer fail to marshal his efforts towards a unified attack upon it. Thus, out of the economic and political disequilibria there grew the attempt to bring nations together to face the food problem which they had in common, first through the old League of Nations and then, on a much larger scale and with broader terms of reference, in the Food and Agriculture Organization of the United Nations* established in 1945. Sired by Hope out of Misfortune, FAO constitutes a response to the stresses brought about by the challenge of this uneasy history. It arose, as did other organisations of this kind, from a growing awareness of interdependence and is a step, though perhaps a tentative one, towards the achievement of some sort of order and management in man's affairs.

THE STATE OF WORLD FOOD SUPPLIES

It will be appropriate at this point to glance at the state of world food supplies, to examine the needs and subsequently to consider what contribution aquatic resources are making, and might make, to the solution of the food problem.

The total food production of the world, based upon the 1952/53 figures (Food and Agriculture Organization of the United Nations,* 1953a) is estimated to have regained the pre-war level per head of the population. As will be seen from

* Hereafter briefly referred to as FAO.

Table 1, the provisional estimates for 1952/53 show an increase of 17 per cent. over the pre-war average in both food production and population.

† Including estimates for U.S.S.R., Eastern Europe and China.

‡ All figures for 1952/53 are provisional.

But these figures of overall production and increases are misleading in that they do not reveal the unevenness of the increase. For instance, nearly half of the increase in world agricultural production since 1934-38 occurred in North America alone, a region which supports only 7 per cent. of the world's population. At the other extreme, the Far East, with about half the world's population, has only maintained its pre-war level of production. Other regions have made a good deal of progress. Latin America, the Near East and

Africa are all producing about one-third more than they did in the pre-war years, and Europe and Oceania have increased their production by from 10 to 20 per cent.

The unevenness of present-day food production is associated with uneven rates of population increase, and hence uneven basic food requirements, in many parts of the world. It is estimated that in Europe and the U.S.S.R. the increase in population has been of the order of 10 per cent. of the 1934-38 average. In China, it has been less than 5 per cent. On the other hand, the Far East (excluding China), North America, Oceania, Africa and the Near East have all increased their population by about 25 per cent., and Latin America by no less than 40 per cent. over the 1934-38 average.

On the per head basis it appears that food production is somewhat above the pre-war level in Europe, Africa and the Near East, and somewhat below it in Latin America and Oceania. In two regions of the world the change in production per head is much more striking. In North America it shows an increase of between 15 and 20 per cent.; in the Far East it is from 15 to 20 per cent. below the pre-war average.

However, the indices used in the above computations tell nothing of the quantities of food produced in the several regions, and the level of production per head reflects only in a general way the level of food consumption. Food consumption cannot be separated from purchasing power. In countries like North America, only about from 30 to 40 per cent. of the wage-earner's income is spent on food; in the Far East most of the resources of the wage-earner are used to obtain a diet which even then is inadequate for himself and his family.

In the underdeveloped areas where population pressures are greatest, the most serious difficulty lies in the quality of the diet, which is characterised by a low level of protective foods. There is no relatively simple unit, such as the calorie, available for the measurement of the quality of diets, and the protein content is perhaps the best available indicator, because most foods rich in protein are also comparatively good sources of other essential nutrients. Since this is particularly true of foods of animal origin, the animal protein intake is probably better than the total protein intake as an indicator.

Table 2 shows a comparison between the pre-war energy and protein content of national average food supplies and those of 1951/52.

It will be noted from this table that in Latin America, with the exception of Argentina and Uruguay, the animal protein intake is low; in Europe it is low in Greece and Italy, and in the Far East and the Near East countries it is very low indeed. It is here that the most serious qualitative

Vol. 24, No. 3

nutritional deficiencies occur and, as can be seen, there are also deficiencies of energy. In addition, it is becoming widely recognised that debilitating diseases such as kwashiorkor or similar syndromes are associated with low intake of protein and especially of protein of animal origin.

The contribution made by fisheries to the food supplies of the world is predominantly animal protein of high biological value, and it is now proposed to examine the magnitude of that contribution.

SUPPLIES OF FOOD FROM FISHERIES

One of the first tasks that confronted FAO was to institute a collection of statistics of world fisheries and to report them in summary form and uniform terminology. Its most recent *Yearbook of Fisheries Statistics* (FAO, 1953b) covers the available information for 1950-51. These data include all material furnished by national governments and conservative estimates of the yields of the subsistence and sport fisheries for which exact figures are not available. Estimates have also been made for the U.S.S.R., from which no statistics are available to FAO.

Table 3 shows that the world production in 1950-51 was about 26 million metric tons, on the basis of the weight of the fish at the time it was caught.

To this must be added over 2000 tons of whales caught each year. But it must be remembered that the whale is caught primarily for its oil, and only a fraction of the protein is used (Kondrup, 1952). It will also be seen that slightly more than 10 per cent. of fish caught is used for the production of oil and meal. Fishmeal, because of its high protein content and the presence of vitamin B₁₂, is widely sought for animal and poultry feeding, and contributes indirectly to human food. The manufacture of these products consumes one-third of the African catch and one-fifth of the catch of Europe and North America.

The bulk of the world catch, because of its limited marketable life, is absorbed by domestic consumption, but developments in preservation and transport have gradually made a wider distribution possible, so that now some 20 per cent. of the world's catch enters international trade. Generally speaking, most of this trade is intra-regional, but some commodities are now exchanged inter-regionally. The developments in Scandinavia and South Africa, in particular, have brought these parts of the world to the position of net exporting regions. The most important individual countries with a net export (FAO, 1953b) are (1950 figures in metric tons): Canada (279,108), Denmark (81,041), French Morocco (78,661), Iceland (141,414), Japan (56,123), Netherlands (12,678), Norway (488,115), Union of South Africa and South-West Africa (44,498).

§ For the purpose of this table this group includes ganoids: sturgeons and garfish.

|| Excluding aquatic mammals (baleen and sperm whales, dolphins, seals and the like).

It will be noted that countries with net exports are among the better developed, and when it is considered that most of the exports go to other well developed countries where purchasing power is high, it can be seen that in general the consumption in the underdeveloped areas, where the needs are greatest, has not been greatly affected.

Consumption of Fishery Products per Head

The problem of estimating the consumption of fisheries products per head presents many difficulties. Even in countries where advanced statistical services exist many assumptions have to be made, and for other areas methods of sampling must be resorted to and approximations made to the average annual consumption of fisheries products by each person.

Nutritionally the problem is further complicated by the fact that the pattern of fish consumption within a country is uneven. Most fish is consumed in places that are near the source of supply, on the borders of the sea or of inland water systems. People who live remote from these places usually eat less fish, with the occasional exception of those in large urban centres where communication and transport systems are much better than in rural areas.

But, taking world production and population as a whole, it will be seen that when the amount used for fishmeal and oil is deducted from the total catch, something less than 10 kg. fish per head per annum is left for human consumption. This is further reduced by manufacturing and other processing so that by the time it is consumed it amounts to only about 5 kg. Total food consumption varies widely in different parts of the world. The Second World Food Survey (FAO, 1952a) shows that, in terms of recent averages at retail level, it was 733 kg. for Sweden, 684 kg. for the United Kingdom, 455 kg. for Venezuela and 252 kg. for India per person per annum. These few examples indicate that fish supplies directly consumed amount to only a fraction of 1 per cent. of the total diet.

For many years FAO, in co-operation with its member governments, has been devoting attention to the preparation of food balance sheets which reveal the composition of national diets and consumption patterns. In November 1952 it published the Second World Food Survey as a progress report. Table 4 is extracted from data presented in this Survey and furnishes an idea of the order of magnitude of fish consumption per head as compared with the consumption of meat, eggs and milk.

In Table 4 the figures under animal protein foods per head include milk, excluding butterfat, but including other milk products in terms of fluid

milk; meat wherever possible is in terms of dressed carcase weight, and fish as fresh landed weight. It will be seen that in the Far East and Africa the animal protein intake is extremely low, and that the contribution that fish makes is small in both regions absolutely and in Africa also as a percentage. Since most fish is consumed near the coasts and rivers, the consumption of the populations living in remote interior regions must be still less.

TABLE 4

GROSS FOOD SUPPLIES IN KG. PER HEAD PER ANNUM OF ANIMAL PROTEIN FOODS * AND FISH, 1946/50, † BY REGIONS

(Computed from FAO, 1952a)

Regions	Animal protein foods	Fish	Fish as percentage of animal protein foods
Far East . . .	34.5	6.6	19.1
Near East . . .	110.2	2.8	2.5
Africa . . .	68.6	2.4	3.5
Latin America . .	141.1	4.9	3.5
Europe . . .	174.7	13.6	7.8
North America and Oceania . . .	502.9	5.2	1.0

* Animal protein foods include meat, fish, milk (as fluid milk) and eggs.

† Extreme limits of the period observed for all regions.

The lack of statistical data in many parts of the world means, of course, that no claim for accuracy can be made for the figures in Table 4, but they are considered to be near enough to illustrate the order of the quantity available and to demonstrate the differences in pattern of consumption.

In calculating basic human dietary requirements, the Second World Food Survey took into account the variation in the needs of people as influenced by climate, energy output in work, sex and age grouping in the units of population considered. It was the aim of this Survey to determine where the deficiencies lay and to indicate where effort in the production of food should be directed. However, in describing the deficiencies and setting the targets, the ultimate ideals of nutritional goals were not used; rather, a point was chosen between what was nutritionally desirable and what it was thought might be feasible in practice.

By using these data and with the most important deficiency, *i.e.*, that of animal protein, in mind, it was calculated that if the total world population increases by 11 per cent. between 1950 and 1960, the percentage increase above recent levels required in gross fish supplies would be 47 per cent., a problem of considerable magnitude.

When this figure of 47 per cent. is examined regionally, it can be broken down as shown in Table 5.

TABLE 5

PERCENTAGE INCREASES REQUIRED IN GROSS SUPPLIES OF FISH TO MEET 1960 TARGETS, AND ESTIMATED PERCENTAGE POPULATION INCREASES BY 1960

(Adapted from FAO, 1952a)

	Fish	Population
Far East	68	10
Near East	50	15
Africa	75	15
Latin America	26	18
Europe	11	8
North America and Oceania	18	14
U.S.S.R.	18	16
World	47	11

The magnitude of these aims is even more clearly revealed when it appears that the greatest increases have to come, as might be expected, in those areas that are least developed economically. So far as the better developed areas are concerned, the opinion is widely held by students of these matters that Europe and North America and Oceania as well as the U.S.S.R. should be fully capable of achieving the aims set forth in the Second World Food Survey by 1960, if indeed they are not already in the position to do so. However, the low purchasing power of most of the consumers in the underdeveloped areas, and the difficulties that face international trade, effectively prevent the use of the productive power of countries in the highly developed areas from making up the shortages in the underdeveloped areas, which are therefore forced to look to improvement in their own production. Another reason for this is to be found in the desire of many countries to be more self-sufficient than they have been in producing their own food. The terrible experience during the second world war of having food imports upon which they were dependent suddenly cut off has engendered this and therefore, even where imported food may be cheaper than that produced locally, there is a tendency to strive for local production.

THE PROSPECT FOR INCREASE IN AQUATIC FOOD

Phytoplankton and Seaweeds

In a recent paper on the contribution of fisheries to world food supplies (FAO, 1953c) it is pointed out that, as on land, the starting point of productivity in the sea is assimilation by plants. Sverdrup (1952) and others believe that the total primary

production of the sea is about equal to that of the land. The comparison is not simple because much food from the land is taken in the plant stage but food from the sea is utilised only to a small degree at this stage of the production chain. That is to say, a much smaller fraction of primary production from the sea is used as human food than from the land.

Assimilation is of course dependent upon the presence of the primary nutrients. Here notice must be taken of the vast accumulation of nutrient materials that lie in the depths of the sea beyond the photosynthetic depths, which as a result of the ocean currents, tides, storms, and temperature changes partly replenish the surface waters. However, there are some reserves which remain undisturbed and unused; these might possibly be brought into use by what may be called artificial upwellings, but the economic and technical aspects of this problem make it something for the remote future. Man's ingenuity might be equal to the task under a sufficient set of compulsions. One might like to speculate on what could be produced by lowering a slow-reacting atomic pile into the depths and allowing mere temperature gradients to accomplish an upwelling, or by harnessing energy to the same end in some other way.

However, to whatever extent the primary production of waters may eventually be increased, it is certain that they could yield considerably more than they do now at the plant stage of the production cycle. Careful surveys have revealed that the quantities of seaweeds taken, although they are considerable, represent only a very small fraction of the measurable stand of weeds. Woodward (1952) estimates that Scotland alone could produce from 70,000 to 110,000 tons of carbohydrates annually from seaweeds. He estimates that 60 million tons of brown seaweed grow on the coasts of Norway, France, the British Isles, Canada and the United States. To compute possible world production would lead to astronomical figures. Beyond this, there are other possibilities for the use of aquatic flora. Weeds from ponds may be used to provide green manure for agricultural land; possible direct or indirect uses may be found for phytoplankton, though it is doubtful whether collecting devices could be made economically feasible.

Zooplankton

Turning to animal life, considerable quantities of small fish, crustaceans and zooplankton are at present used by Asian countries for the manufacture of savoury pastes and sauces (van Veen, 1953). Possibly some use could be made of the immense quantities of zooplankton that inhabit the Antarctic and support the whale populations.

N.A. and R., July 1954

The quantities consumed by whales are enormous (Discovery Reports, 1929; 1935), and though it is unlikely that exploitation of this particular resource could be made economically feasible, the possibility should not be overlooked.

Marine Fish

As far as existing fisheries go, it seems unlikely that the yield need fall below its present level. It is true that certain species in restricted localities such as the North Sea, the halibut of the north-western shores of North America and the whale stocks in the Antarctic are in danger of overfishing and depletion. These fisheries are regulated by international agreement, and this is tending to maintain the present level of production. It is not improbable that under such agreements the economic return from these fisheries will be increased, and that international planning and management will mean greater efficiency.

This is illustrated by a statement of the Ministry of Agriculture and Fisheries (1953b) in London that "Taking three main species—plaice, haddock and cod, the estimate comes out that about half the fishing of the 1930's would give twenty per cent greater weight from the North Sea, over a run of years. Steps in that direction would give gains in proportion: more and better fish with less time spent on catching them." This is in line with the concept of management developed by Graham (1935). His argument is that unplanned fishing not only adversely affects the fish population, which, of course, manifests itself in the catch, but also means an avoidable waste of effort. Redistribution of fishing power would serve to bring the effort nearer to the sustained yielding power of the resources, and would also confer economic advantages on the fleet and liberate effort which could be used on resources that are underdeveloped.

For the most part, fishing is confined to the continental shelves, which together form only 10 per cent. of the marine area (Kask, 1951), but there are indications that fishing in other regions for pelagic species is on the increase, particularly for such species as tuna and herring-like fish. New methods of fish detection and new knowledge about fish behaviour are making it increasingly possible to add to the catches of these species. There is some indication that the fluctuations in production are in large part due to economic factors, and that output could be increased if these could be controlled (FAO, 1949). In other cases fluctuations in yield seem to be due to natural causes, as, for example, with the Californian sardine (Clark and Daugherty, 1950; California Department of Fish and Game, Marine Research Committee, 1952), the Atlantic sardine (Furnestin, 1952) and the Indian

oil sardine (Nair and Chidambaram, 1951), though with the last, inefficiency of the existing gear also plays a part. At present it is believed that the stocks of fish in several parts of the world are underexploited. Among these are the Arabian Sea and the Persian Gulf for anchovy and similar species (Blegvad and Løppenthin, 1944), and the southern waters off Australia and the west coast of South America, and the English Channel, for pilchards (Fiedler *et al.*, 1943; Blackburn, 1951; Ministry of Agriculture and Fisheries, 1953a). While the exploitation of these stocks would undoubtedly vary in yield and regularity, it is certain that additional yields could be obtained of the order of many thousands of tons per annum. An example of this is the pilchard fishery off South Africa, which in eight years has risen from nothing to 400,000 tons a year, and is thought to be capable of still further expansion (Gertenbach, 1953). Then again, with reference to flat fish, Walford (1951) maintains that only 10 per cent of the known plaice grounds are being fished, an estimate which holds possibilities of important increases. It may be assumed that similar prospects exist for other species of this group. Sharks and other elasmobranchs offer possibilities, especially in neglected areas such as the Red Sea (Marshall, 1952).

Crustaceans and Molluscs

Crustaceans and molluscs constitute another part of the total aquatic resources that are now being more extensively exploited and hold possibilities of further expansion. During the last few years new stocks of crustaceans have been located and have given rise to new fisheries off the American east coast (Walford, 1948; Anderson *et al.*, 1950), off the east coast of Australia (Commonwealth Director of Fisheries, Australia, 1950a) and in the Gulf of Mexico (Springer and Bullis, 1952). Crayfish have been exploited in South Africa (Gertenbach, 1953) and Western Australia (Sheard, 1949; Commonwealth Director of Fisheries, Australia, 1950b). Other obvious places for increased exploitations are in the Bay of Bengal, off the mouths of the Ganges and Godavari rivers. The Indus and the mouths of rivers of New Guinea and Borneo would offer similar opportunities.

Thus for the sea fisheries we see that although among the existing fisheries there are some that would not produce substantially more but in which, nevertheless, greater efficiency and economy of effort could be obtained, there are others that could yield more and are underexploited, and still others that are neglected. Certain resources such as the phyto- and zoo-plankton may be further developed.

Freshwater Fish : Fish Culture

Inland waters constitute another section of the aquatic resources in which increased production will certainly take place. It is estimated that 4-6 million tons of freshwater fish are taken annually. This includes substantial fishing of the wild stocks in the lakes and rivers of the Asian continent (including China) and Latin America; the commercial fishery of the Great Lakes of North America; rivers and lakes in British East Africa, Europe, China and Cambodia; and the cultural operations in fresh and brackish waters of China, India, Japan, Taiwan, the Philippines and Indonesia. Fish culture has undoubtedly existed for many hundreds of years in parts of Asia, and the arts of it were passed down from father to son or from master to apprentice. But it was an art rather than a science; the techniques were perfected in relation to a certain set of conditions, laboriously worked out by a process of trial and error that must have lasted for centuries. Little, if anything, was known of the reasons why things worked; it was sufficient that they did. Thus, when it came to transferring the knowledge to a new set of conditions, difficulties and failures were encountered. Of recent years scientists have intensified their study of the basic principles involved and a scientific basis for the art of fish culture is being worked out. It is becoming increasingly possible to work in new conditions and to bring into use waters that once lay idle and unmanaged. The great reservoirs and canal systems required by irrigation, the swampy areas, the salt marshes unfit for agricultural production, can all be put into use as producers of fish. For the Indo-Pacific region alone it is estimated that there are 37 million hectares (FAO, 1952b) of cultivable inland waters. If all this were put into use and even a very modest average yield were achieved, a substantial total would result.

Fish culture in inland water systems has many advantages for the economically underdeveloped areas. The problems of transport, preservation and complex marketing systems are reduced to a minimum. The fish may be reared where it is needed and harvested at the moment it is required. Under special conditions which prevail in such places as Haiti, where there were no predator fish amongst the relatively sparse fauna of the inland water systems, the rough release of fry reared in recently established breeding ponds under the guidance of FAO has led to a great increase in fish population and of production by the peasant farmers. The whole of Central America could undoubtedly add to its indigenously produced animal protein by fish culture operations. Similar results have been produced in Thailand. A notable yield of freshwater fish is obtained by

cultivation in wet rice paddies, and it is reported that not only is a protein crop obtained, but the yield of rice is increased by about 7 per cent (Schuster, 1954). Much more work of this type could be done in India, Egypt, Burma and elsewhere.

Thus, taking into account the possibilities of further exploitation in the sea, and remembering that the fresh and brackish waters of the world could produce much more, there seems to be no reason, from the biological point of view, why fisheries should not yield much more food than they do at present.

The technical ability of man to take advantage of what is biologically possible is also advancing. The use of echo sounding and of asdic for fish finding is widely practised and new refinements are constantly being added. Studies of the behaviour of a fish, its reactions to environment and its migratory habits are making it increasingly possible to predict its presence. A fuller understanding of how fishing gear works and the design of new fish-catching apparatus are improving the chances of catching it once it is found. The use of under-water electric fields to control the movements of fish, to fence them in, so to speak, is already being tried with some hope of success (Tester, 1952; Meyer, 1953). In many of the economically underdeveloped countries fishermen are changing from sail to mechanical propulsion. This not only enables them to tap hitherto unused resources, but reduces the weather hazard because they are able to accomplish their task more rapidly.

Advances are being made in fish handling also. Much work is being undertaken on better methods of fish preservation, and it is becoming increasingly possible to reduce waste from spoilage of this most perishable food product. Fish that were previously unmarketable are now presented to the consumer in different, acceptable forms. In the United States a whole new industry was created in New England by the successful marketing of skinned fillets of rose fish, a fish which was unacceptable in a merely "dressed" state. The landings increased from 120 tons in 1932 to over 94,000 tons in 1950. In other instances, improvements in freezing and transport have widened markets. A newer development is to be found in the marketing of fish pre-cooked. Two-ounce portions of fresh fish are breaded and fried, and then rapidly frozen. Subsequent warming is all that is necessary to produce an appetising dish.

At the opposite end of the scale, experiments in the manufacture of dehydrated fish protein in the form of "fish flour" have indicated that this substance may be incorporated in bread without

any adverse reaction from the consumer. If this can be made commercially feasible, a relatively cheap and convenient way will have been found to raise the animal protein intake and enrich an otherwise predominantly carbohydrate diet. The acceptability of commercially produced fishmeal added to rice and other high-carbohydrate diets, such as are prevalent in Asia, is also being tested, with promising results. If such measures are successful, a good many problems connected with transport and storage will be made easier and the reduced costs should result in prices within the means of more people.

Efforts are also being directed towards the improvement of marketing and distribution, and though much in this direction remains to be done even in the most advanced countries, increasing attention is being paid to the problems involved.

And so it seems that technologically as well as biologically there is no reason why the supply of fish as food should not be greatly increased. In the United States the catch has steadily risen from an average of 1.4 million tons in 1930-34 to 2.2 million tons in 1950 and no physical reason is foreseen why further increases of this proportion could not take place in future. Again, the U.S.S.R. (Department of Fisheries, Canada, 1953) in the current Five Year Plan hopes to raise the catch to more than twice that of 1950. The Japanese Fisheries Agency has predicted that Japan's production of fish will reach 5 million tons in 1957 (Neville, 1953).

It will be noted that these countries are in the forefront of technical and economic development, and it would not be safe to conclude that the less developed countries, where the biggest needs lie, will achieve increases of this order. Nor would it be safe to take for granted that what is physically possible in increased production, will actually take place in these better developed countries. Fisheries products are particularly vulnerable to competition from other foods and the demand for most of them shows considerable elasticity. Then again, production in the better developed parts of the world is considerably influenced by the opportunities of international trade, and protective policies, currency difficulties and similar impediments may operate to restrict production.

In the underdeveloped countries, the strategic importance of fisheries products in the diet may cause the adoption of policies that are quite different from those in the better developed. Here it must be remembered that the supply of animal protein from agricultural sources is extremely limited. The relation of the area of arable land to the population density precludes the use of

pasture and the feeding of animals on cereals, but the production of fish does not encroach on the growth of cereals or vegetable food products. On the other hand, the lack of modern skills and of the capital apparatus which they require constitutes a barrier to development that can usually be overcome only by special intervention of governments.

It is here that the Food and Agriculture Organization can be of assistance. It assists governments to assess local resources and determine the possibilities for their development, it helps to put into motion a set of incentives which can operate through some form of organised structure which will get production under way, and it aids in the achievement of methods of distribution and consumption suited to the prevailing conditions.

However, fisheries problems cannot be dealt with in isolation and apart from the general level of economy. Any increase in consumption of animal protein which fisheries could supply, by people who are really in need of it will, to a large measure, depend upon a general heightening of effective economic activity such as is the aim of all programmes of technical assistance.

The Final Act of the Hot Springs Conference (United Nations Conference on Food and Agriculture, 1943) opens with a Declaration, from which paragraphs 3 and 4 are quoted:

"There has never been enough food for the health of all people. This is justified neither by ignorance nor by the harshness of nature. Production of food must be greatly expanded; we now have knowledge of the means by which this can be done. It requires imagination and firm will on the part of each government and people to make use of that knowledge.

"The first cause of hunger and malnutrition is poverty. It is useless to produce more food unless men and nations provide the markets to absorb it. There must be an expansion of the whole world economy to provide the purchasing power sufficient to maintain an adequate diet for all. With full employment in all countries, enlarged industrial production, the absence of exploitation, an increasing flow of trade within and between countries, an orderly management of domestic and international investment and currencies, and sustained internal and international economic equilibrium, the food which is produced can be made available to all people."

This statement is just as true today as it was when it was made in 1943. It is particularly true of fisheries and the contribution they could make to world food supplies.

CHEMICAL

APPARATUS

2691

FAJKOŠ, L. Automatizace chromatografických prací. [Automatic chromatographic procedures.] *Chem. listy*, 1953, **47**, 630-631. [Inst. Organ. Chem., Czech. Acad. Sci., Prague.]

The construction of a new apparatus for automatic chromatographic procedures is described. The apparatus consists of a rotating disc, with receiving vessels and siphon, for collecting consecutive fractions of eluate.—A. Jančařík (Czechoslovakia).

2692

WUNDERLY, C. A trough for paper chromatography consisting of segments. *Nature*, 1954, **173**, 267-268. [Med. Clin., Univ. Zürich.]

The trough described makes it possible to perform separations under identical conditions. Examples of its use include the study of the effect of variations in pH and ionic strength on the movement of various compounds.—H. G. Bray.

2693

MITCHELL, L. C. A tank for 8 × 8 inch paper chromatograms. *J. Assoc. Off. Agric. Chem.*, 1953, **36**, 1187-1188. [Dept. Health, Education and Welfare, Washington 25, D.C.]

Details of construction are given, the 8 × 8 in. size having been chosen because the time for development with many mobile solvent systems is within a range of 1 to 4 hr. and on such a sheet 7 or 8 samples can be spotted, without crowding, for one-dimensional development.—D. Harvey.

2694

POLSON, A. An electrophoresis cell for analysing four samples simultaneously. *Biochem. biophys. Acta*, 1954, **13**, 451-452. [Virus Res. Unit, Dept. Pathol., Univ. Cape Town.]

2695

CANNON, J. R. and GILSON, A. R. A simple apparatus and technique for preparative paper electrophoresis. *Chem. and Indust.*, 1954, No. 5, 120-121. [Univ. Chem. Lab., Pembroke St., Cambridge.]

A variation of the type of apparatus used for descending paper chromatography. The apparatus and procedure are described in detail.

H. G. Bray.

2696

PODROUŽEK, V. Jednoduché zařízení k hodnocení papírových elektroferogramů. [A simplified

Vol. 24, No. 3

apparatus for evaluation of paper electropherograms.] *Čsl. Fysiol.*, 1953, 312-314.

A simplified photometric apparatus for evaluation of paper electropherograms is described.

A. Jančařík (Czechoslovakia).

2697

BRADA, M. and BRADA, Z. Zařízení ke kvantitativní mikrospektrografii. [A new apparatus for quantitative microspectrography.] *Čsl. Fysiol.*, 1953, 433-438. [Dept. Biochem., Masaryk's Radiotherap. Inst., Brno.]

With the exception of the source of monochromatic light, which may be replaced by suitable light-filters, only easily obtainable parts were used for the construction. Novák's sensitometer was used for the final measurements. The results obtained are in good agreement with those obtained by other methods.—A. Jančařík (Czechoslovakia).

ANALYTICAL METHODS

General

2698

IRREVERRE, F. and MARTIN, W. Versatile technique of paper chromatography. *Anal. Chem.*, 1954, **26**, 257-260. [Nat. Inst. Arthritis and Metabol. Dis., Bethesda, Md.]

The rate of solvent flow in descending paper chromatography can be varied over a wide range by means of a system of "wicks", which is described.—H. G. Bray.

2699

SCHWERDTFEGGER, E. Modifizierte eindimensionale Papierchromatographie für quantitative Zwecke. [Modified one-dimensional paper chromatography for quantitative work.] *Naturwissenschaften*, 1954, **41**, 18. [Oskar-Kellner-Inst. Tierernährung, Rostock.]

A technique is described in which the paper sheet is cut so that the spots of the samples to be treated are applied at points situated on "bridges" between the main body of the paper and the horizontal strip which is immersed in the developing solvent when applying descending chromatography. Mixtures which give continuous streaks when the usual procedure is applied give bands.

H. G. Bray.

2700

MATTHIAS, W. Serienuntersuchungen mit Hilfe einer neuen Form der Streifen-Papierchromatographie. [Serial experiments with a new type

of paper strip chromatography.] *Naturwissenschaften*, 1954, **41**, 17-18. [Inst. Pflanzenzücht. Quedlinburg, Deutsch. Akad. Landwirtsch., Berlin.]

A sheet of paper is cut so that there are at the lower end pointed projections equal in number to the number of samples to be investigated. The samples are applied to the points and the chromatogram is developed by an ascending technique. The bands from each sample behave independently and their size and intensities are readily compared.

H. G. Bray.

2701

DICASTRO, G. **Some remarks on two-dimensional paper electrophoresis.** *Experientia*, 1954, **10**, 27-28. ["Medital" Labs. Res. Div., Rome.] Italian summary.

A detailed description of a technique.

H. G. Bray.

2702

DVOŘÁK, J., GRUBNER, O. and ŠPURNÝ, Z. Protid-proudová kontinuální elektroforesa na papíře. Předběžné sdělení. [Counterstream continuous electrophoresis on filter paper. A preliminary communication.] *Chem. listy*, 1953, **47**, 899-900. [Physik.-Chem. Inst., Karl's Univ., Prague.]

A new method for electrophoresis, based on the fact that the particles, charged with electricity, are drawn by the electric current against the stream of an electrolyte flowing down a plane, the inclination of which can be varied.

M. Prokšová (Czechoslovakia).

Carbohydrate Constituents

2703

GAILLARD, B. D. E. De papierchromatografie van suikers. [Paper chromatography of sugars.] *Pharm. Weekblad*, 1953, **88**, 629-641. [Lab. Physiol. Dieren, Landbouwhogeschool, Wageningen.]

A detailed working account is given of the chromatography and electrophoresis of sugars on paper.—I. Leitch.

2704

BARKER, G. R. and SMITH, D. C. C. **Paper chromatography of some carbohydrates and related compounds in the presence of boric acid.** *Chem. and Indust.*, 1954, No. 1, 19-20. [Dept. Chem., Univ. Manchester.]

BARNES, H. D. and BLOOMBERG, B. M. **Paper chromatography of the urinary sugar in essential pentosuria.** *S. African J. Med. Sci.*, 1953, **18**, 93-98. [Biochem. Dept., S. African Inst. Med. Res., Johannesburg.]

2709

HONER, C. J. and TUCKEY, S. L. **A method for determination of lactose in milk by paper chromatography.** *J. Dairy Sci.*, 1953, **36**, 1233-1240. [Dept. Food Technol., Univ. Illinois, Urbana.]

Diluted milk is applied directly to filter paper (Whatman No. 1) and subjected to descending chromatography, with a mixture of ethyl acetate, pyridine and water (2.5 : 1 : 3.5) as solvent. Two spots are run simultaneously on the same strip. After 24 hours' development the strip is dried and cut lengthwise. On one half the sugars are located by means of AgNO₃ in acetone. The other half is cut lengthwise into 6 strips and in each the lactose is located by reference to the treated strip. The zones judged to contain

N.A. and R., July 1954

lactose are cut into segments and each is treated in a boiling-water bath with potassium ferricyanide, sodium carbonate and potassium cyanide. Ferric sulphate and gum arabic are then added and the colours produced are read in a spectrophotometer. In control experiments where lactose was added to milk the average recovery was 95, range 92 to 97 per cent.—H. G. Bray.

2710

SKELL, P. S. and CRIST, J. G. **A rapid gasometric method of analysis for "reducing" sugars and other carbonyl compounds.** *Nature*, 1954, **173**, 401. [Dept. Chem., Pennsylvania State Univ.]

2711

WAGER, H. G. **An improved copper reduction method for the micro-determination of reducing sugars.** *Analyst*, 1954, **79**, 34-38. [Low Temp. Res. Stat., Univ. Cambridge.]

Errors in the Nelson method (Abst. 849, Vol. 14) were shown to be due to oxidation reactions brought about by atmospheric oxygen and to the instability of the blue colour finally formed. Modifications are suggested, including the use of an oxygen-free atmosphere and the measurement of the extinction coefficient of the final solution after a standard time. An apparatus is described for heating and cooling the reaction mixture under nitrogen.—H. G. Bray.

2712

LANDGREBE, F. W. and MUNDAY, K. A. **A modified Folin-Malmros technique for the estimation of blood sugar, particularly suitable for low values or for micro work.** *Quart. J. Exp. Physiol.*, 1954, **39**, 17-22. [Dept. Materia Med., Welsh Nat. Sch. Med.]

Blood proteins are precipitated by dilute tungstic acid and the supernatant is treated with ferricyanide and alkaline cyanide. The ferrocyanide produced by reduction is converted by means of ferric chloride to Prussian blue, which is estimated colorimetrically. By the procedure described 12 samples can be dealt with in 45 min. Normal concentrations of blood glucose can be estimated within 2 per cent. and 2 to 3 μ g. to within 5 per cent. As little as 0.01 ml. blood may be used.—H. G. Bray.

2713

BADIN, J., JACKSON, C. and SCHUBERT, M. **Improved method for determination of plasma polysaccharides with tryptophan.** *Proc. Soc. Exp. Biol. Med.*, 1953, **84**, 288-291. [Dept. Chem., Coll. Med., Univ. New York.]

The polysaccharide is treated with a mixture of boric and sulphuric acids and, after cooling, trypto-

phan is added. The mixture is heated in a boiling-water bath and the violet colour produced is measured photometrically.—H. G. Bray.

2714

GRANDE, F., UTRERA, A. and DE OYA, J. C. **La reaccion de la antrona en la determinacion de los hidratos de carbono. [The anthrone reaction in the estimation of carbohydrates.]** *Rev. clin. española*, 1953, **51**, 17-23. [Inst. Invest. Med., Madrid.] English, German and French summaries.

The reaction of anthrone with carbohydrates was studied, with particular attention to the precautions necessary in applying the reaction to the quantitative estimation of carbohydrates. The application of the anthrone method to the estimation of glycogen in biological tissues is fully described. The results obtained agree closely with those obtained by the classic method of Good, Kramer and Somogyi. With regard to the mechanism of the reaction, the available data indicate that it is produced by the condensation of anthranol with methyl- or hydroxymethylfurfural. The method is useful in biochemical analysis not only for glycogen estimation, but in blood sugar estimations, since it is not affected by the presence of reducing substances other than sugars which interfere in other methods.—M. B. Richards.

2715

WALLENUS, G. **Some procedures for dextran estimation in various body fluids.** *Acta Soc. Med. upsalien.*, 1953, **59**, 69-77. [Central Lab., Univ. Hosp., Upsala.]

Procedures for the estimation of dextran are outlined. For low concentrations the anthrone method is considered most satisfactory, and full details are given of a modified procedure used for the analysis of serum, ascites or similar body fluids. For the specific detection of dextran a serological method is described which can be used for the semi-quantitative estimation of small amounts.—M. B. Richards.

2716

KAHAN, J. **A rapid photometric method for the determination of glycogen.** *Arch. Biochem. Biophys.*, 1953, **47**, 408-418. [Pharmacol. Dept., Karolinska Inst., Fac. Med., Stockholm 60, Sweden.]

A trichloroacetic acid extract of the tissue is treated with baryta to remove interfering substances, excess Ba is precipitated with zinc sulphate and the clear supernatant is treated with an H_2SO_4 -anthrone reagent, and the colour formed is estimated photometrically. From 2 to 300 μ g. glycogen can be estimated to within ± 2.6 per cent.—H. G. Bray.

2717

HERBAIN, M. Le microdosage du glycogène hépatique. Son application aux prélèvements biopsiques. [Micro-estimation of liver glycogen. Its application to biopsy samples.] *Bull. Soc. Chim. biol.*, 1953, **35**, 1421-1436. [Lab. Pathol. Exp., Fac. Méd., Paris.]

Two procedures are described, one applicable to 15 to 20 mg. tissue and the other to 3 to 4 mg. In the first glycogen is isolated by ethanolic precipitation and hydrolysed and the glucose formed is estimated colorimetrically by a Prussian blue reaction. In the second method the glycogen:nitrogen ratio of the sample is estimated and from this the glycogen content of the whole liver is deduced.—H. G. Bray.

2718

D'ARCY, R. A. A routine method for estimating the starch content of wheat by-products. *Cereal Chem.*, 1954, **31**, 37-42. [Dublin Port Milling Co., Ltd., Ireland.]

Soluble carbohydrates are removed by 2 per cent. HCl and the residue is hydrolysed. The reducing power of the hydrolysate is then estimated before and after fermentation by yeast.

H. G. Bray.

2719

MACDOUGALL, D. The determination of lignin in plant tissues: use of a continuous-extraction method to remove interfering materials. *J. Sci. Food Agric.*, 1954, **5**, 103-107. [Dept. Chem., Ontario Agric. Coll., Guelph, Ont.]

The removal of contaminating carbohydrate and nitrogenous fractions of plant material was accomplished by 6-hr. continuous extraction in a Soxhlet extractor with 1 per cent. HCl. The isolated lignin contained less N and had a lower methoxyl content than that isolated by the standard A.O.A.C. pre-treatment.—D. M. Walker.

SHORT, E. I. The estimation of total nitrogen using the Conway micro-diffusion cell. *J. Clin. Pathol.*, 1954, **7**, 81-83. [Wellcome Res. Labs., Biol. Div., Beckenham, Kent.]

An adaptation of the original method, employing the reagents used for blood urea estimations. Results obtained in control experiments with serum and urine are given, showing the overall mean recovery to be between 98.8 and 101.2 per cent.—H. G. Bray.

2723

PARKS, T. D., BASTIN, E. L., AGAZZI, E. J. and BROOKS, F. R. Improved micro-Dumas method and apparatus. *Anal. Chem.*, 1954, **26**, 229-232. [Shell Development Co., Emeryville, Calif.]

The sample is vaporised in a stream of CO_2 and organic gases are oxidised by passage over nickel oxide at 1000° , CO by passage over hopcalite at 110° and traces of methane by passage over active copper oxide at 700° C. The incompletely oxidised residue is finally oxidised by oxygen. The nitrogen liberated is collected over KOH in an azotometer and its volume measured by weighing an equal volume of mercury displaced. The apparatus required is described. In examples given the deviations from the theoretical value were, in general, less than 1 per cent. of the actual value.—H. G. Bray.

SAIFER, A. and ORESKES, I. Circular paper chromatography. 2. Isatin as a colour reagent for amino acids. *Science*, 1954, **119**, 124-125. [Biochem. Dept., Div. Labs., Jewish Sanit., Brooklyn, N.Y.]

The dried developed chromatogram is dipped in a solution of isatin, 0.2 per cent. in acetone containing 4 per cent. acetic acid, dried in air and then heated at 100°C. for 10 min. Under these conditions 12 of 21 common amino-acids give colours described as blue (proline, histidine, aspartic acid), blue-green (phenylalanine, tyrosine, tryptophan, hydroxyproline), lavender (glutamic acid, lysine, arginine) and blue-grey (cystine). The particular usefulness of this reagent in circular paper chromatography lies in the fact that of the amino-acids that travel in pairs in some solvents (tyrosine and alanine, valine and methionine) only one of each pair gives a colour.—H. G. Bray.

2734

CURZON, G. and GILTROW, J. **Aromatic aldehydes as specific chromatographic colour reagents for amino-acids.** *Nature*, 1954, **173**, 314-315. [Dept. Biochem., Inst. Orthopaedics, Brockley Hill, Stanmore, Middlesex.]

Dried chromatograms were dipped in acetone or *n*-butanol solutions of aldehydes and heated, and the appearance of spots was recorded in daylight or ultraviolet light. Vanillin gave a red colour with ornithine and amino-acids after the chromatogram was dipped in 1 per cent. ethanolic KOH. *o*-Phthalaldehyde gave a green or purple spot with glycine, according as urea was present in the developing solvent or not, and coloured spots in ultraviolet light with glutamic acid, taurine, histidine, tryptophan and tryptamine. Terephthalaldehyde in acetone solution was found to be a specific reagent for histidine, tryptophan and tryptamine, giving spots of different colours, visible in ultraviolet light.—H. G. Bray.

2735

SMITH, D. C. and TOMPSETT, S. L. **The quantitative determination of amino-acids in urine used in conjunction with one-dimensional paper chromatography.** *J. Clin. Pathol.*, 1954, **7**, 79-80. [Biochem. Lab., Northern Gen. Hosp., Edinburgh.]

One-dimensional paper chromatograms are cut horizontally into 10 equal strips and the amino-acids in each are estimated by a ninhydrin method. H. G. Bray.

SCHLÖGL, K. and WAWERSICH, E. **Eine Methode zur gleichzeitigen Bestimmung der amino- und carboxylendständigen Aminosäure in Peptiden. [A method for the simultaneous estimation of terminal amino and carboxyl amino-acids in peptides.]** *Naturwissenschaften*, 1954, **41**, 38-39. [Chem. Lab., Univ. Vienna.]

An *N*-carbobenzoxytripeptide is heated at 100° C. for 4 to 6 hr. with hydrazine hydrate to give the hydrazide of the central amino-acid and the dihydrazide of the terminal NH₂ amino-acid, the terminal COOH amino-acid being unsubstituted. One portion of the reaction mixture is treated with benzaldehyde or acetone in order to estimate the unsubstituted acid. Another portion is heated in water for 10 to 20 min., whereupon the dihydrazide undergoes ring closure and the triazine or amino-hydantoin formed is extracted with ether from the acidified reaction mixture and estimated chromatographically.—H. G. Bray.

2738

GRASSMANN, W., HÖRMANN, H. and ENDRES, H. **Eine Verbesserung der Bestimmung von Aminosäuren am Carboxylende von Peptiden durch Reduktion der Carboxylgruppe. [An improvement in the estimation of terminal carboxyl amino-acids of peptides by reduction of the carboxyl group.]** *Chem. Ber.*, 1953, **86**, 1477-1482. [Max-Planck-Gesellschaft., Regensburg.]

The terminal carboxyl groups of the peptides are esterified and reduced with LiBH₄. The product is hydrolysed with dilute HCl and the resulting amino-acids and amino-alcohols are converted to their dinitrophenyl derivatives. The dinitrophenylamino-alcohols can be separated quantitatively from the amino-acid derivatives by paper chromatography and identified.

SCANU, A. Curve di frazionamento delle proteine sieriche con il metodo dell'iposolfito sodico. 1. Sieri umani normali. **[Fractionation curves of serum proteins by the sodium hyposulphite method. 1. Normal human sera.]** *Riv. Ist. sieroterap. ital.*, 1953, **28**, 539-549. [Ist. Patol. Spec. Med., Univ. Naples.] English summary.

Fractionation of proteins by salting out with Na thiosulphate was done on 20 normal human sera from 10 males and 10 females, using the salt in concentrations from 17 to 50 per cent., with 1 per cent. increments. When the average values for the protein content of the filtrate, estimated colorimetrically, were plotted against the corresponding saline concentrations, the curves for both males and females showed three main points of inflection at salt concentrations of 30.7, 36.4 and 42.4 per cent., thus permitting the separation of the serum proteins into 4 distinct fractions, presumably analogous to those obtained by electrophoresis. The real existence of these points of inflection was confirmed by their exact correspondence with three inflections in the curves of differentiation constructed according to Majoor (Abst. 2906, Vol. 17), and further confirmation was provided by a study of the statistical data. The author points out certain theoretical and practical advantages of using Na thiosulphate in the salting-out technique instead of other salts more commonly used, such as the sulphate or sulphite.—M. B. Richards.

2744

ORVIN, V. I. Sopostavlenie rezultatov opredelenii albumina i globulinov syvorotki krovi metodami elektroforeza i solevogo osazhdeniya. **[Comparison of the results of estimation of serum albumin and globulin by electrophoresis**

Vol. 24, No. 3

and by salt precipitation.] *Biokhimiya*, 1953, **18**, 329-334. [Inst. Zhivot., Akad. Nauk Tadzhik. SSR].

The ratio of albumin to globulin in blood serum from normal human subjects or rabbits, or from rabbits with diseased livers, as estimated by electrophoresis, did not agree with that obtained by precipitation with 21 or 24 per cent. sodium sulphate. If the concentration of the sulphate was increased to 26.9 per cent. the agreement was better. In the blood serum of rabbits whose livers were damaged by subcutaneous injection of CCl_4 there was a large increase of β - and γ -globulin and a decrease of albumin.—W. Hughes.

2745

PENCE, J. W., WEINSTEIN, N. E. and MECHAM, D. K. **A method for the quantitative determination of albumins and globulins in wheat flour.** *Cereal Chem.*, 1954, **31**, 29-37. [W. Reg. Res. Lab., Bur. Agric. Indust. Chem., U.S. Dept. Agric., Albany, Calif.]

The method depends on the assumption that certain values of the amide N and tryptophan N content of albumins, globulins and gliadin are typical. Soluble proteins are extracted from flour with saline, and total N, N.P.N., tryptophan N and amide N are estimated in the extract. The desired values are then derived algebraically.—H. G. Bray.

Lipoid Constituents

2746

RUSIN, I. M. and SARAİKINA, P. F. Opređenje žira v prostokvashe, atzidoofilne i kefire. **[Estimation of fat in curdled milk, acidophilin and kephir.]** *Vop. Pitan.*, 1954, **13**, 30-32. [Inst. F. F. Erisman, Moscow.]

The accuracy of methods for measuring the fat content of fermented milk products was investigated and causes of discrepancy between methods were estimated. When such errors were eliminated, it was found that there was no appreciable difference between the fat content of such products as curdled milk, acidophilin, and kephir and the original milk samples from which they were prepared.—D. W. Taylor.

2747

MAXCY, R. B. and SOMMER, H. H. **Fat separation in evaporated milk. 1. Homogenization, separation, and viscosity tests.** *J. Dairy Sci.*, 1954, **37**, 60-71. [Dept. Dairy Food Indust., Univ. Wisconsin, Madison.]

2748

BORGSTRÖM, B. **Investigation on lipid separation methods. 3. Separation of tri-, di-, 1-mono- and 2-mono-glycerides.** *Acta physiol. scand.*,

1954, **30**, 231-239. [Dept. Physiol. Chem., Univ. Lund.]

By means of a column of silicic acid and elution with a mixture of benzene with increasing amounts of chloroform, mixtures of tri-, di- and monoglycerides were effectively separated. Partial isomerisation of 2-monoglycerides occurred on the column. Mixtures of 1-mono- and 2-monoglycerides were separated from tri- and di-glycerides by partition chromatography with a mixture of heptane and 80 per cent. aqueous ethanol as solvent. For the resolution of monoglyceride mixtures the 1-monoglycerides were first oxidised with periodic acid, after which the oxidation product formed could be separated from the unchanged 2-monoglyceride by chromatography on a silicic acid column; benzene was used to elute the oxidation product and chloroform to remove the unchanged component.—G. A. Garton.

2749

HADORN, H. and JUNGKUNZ, R. Beitrag zur Bestimmung der Peroxydzahl. [Estimation of peroxide number.] *Mitt. Geb. Lebensmittel. Hyg.*, 1953, **44**, 495-500. [Lab. VSK, Basle.] French and English summaries.

Lea's original method (Abst. 374, Vol. 1) as modified by the authors (*Mitt. Geb. Lebensmittel. Hyg.*, 1951, **42**, 284) has been further modified so that much smaller amounts of KI are needed. The whole procedure is carried out in one vessel in an atmosphere of CO₂. The value of the index for judging the quality and stability of fats and oils is briefly discussed.—W. Godden.

2750

HARTMAN, L., HOOKER, C. N. and WATT, H. E. Colorimetric estimation of fat peroxides in meat. *N.Z. J. Sci. Technol. [B]*, 1954, **35**, 307-310. [Fats. Res. Lab., Dept. Sci. Indust. Res., Wellington.]

The method described is a modification of that of Hartman and Glavind (*Acta chem. scand.*, 1949, **3**, 954). The fat is extracted from the fresh meat by a mixture of equal volumes of *n*-propanol and xylene and the peroxide is estimated by measuring the extinction coefficient of the leuco base of dichlorophenolindophenol after interaction with the extracted fat. The method is rapid and does not call for the drying of the meat, and phosphatides do not interfere. It is not so accurate as the longer ferric thiocyanate method as modified by Smith (Abst. 137, Vol. 22).—W. Godden.

2751

oils of Cruciferae in edible oils by the lead salt method.] *Mitt. Geb. Lebensmittel. Hyg.*, 1953, **44**, 453-466. [Lab. VSK, Basle.] French and English summaries.

2752

BURTON, H. S. Separation of volatile acids by paper chromatography. *Nature*, 1954, **173**, 127. [Sir William Dunn Sch. Pathol., Univ. Oxford.]

The procedure described by Hiscox and Berridge (Abst. 4623, Vol. 20), in which the acids are applied to the paper as their ethylamine salts and the chromatogram is developed with aqueous butanol, is used. The paper is dried in a stream of air and a spray of bromocresol green is applied just behind the receding solvent front formed as the solvent evaporates. A faint blue background is produced with deep blue spots where acid is located.

H. G. Bray.

2753

SILK, M. H. and HAHN, H. H. The resolution of mixtures of C₁₆-C₂₄ normal-chain fatty acids by reversed-phase partition chromatography. *Biochem. J.*, 1954, **56**, 406-410. [Nat. Chem. Res. Lab., S. African Coun. Sci. Indust. Res., Pretoria.]

With the technique of Howard and Martin (Abst. 1353, Vol. 20), mixtures of palmitic, stearic, arachidic, behenic and lignoceric acids were effectively separated on a semi-quantitative scale. Resolution of normal-chain and corresponding iso-acids was not possible, as was evidenced by the failure to separate a mixture of stearic and 16-methylheptadecanoic-acids. Good qualitative separation of the unsaturated fatty acids of pilchard oil was obtained.—G. A. Garton.

2754

HILLIG, F. Rapid method for the estimation of water-insoluble fatty acids (WIA) in cream and butter. *J. Assoc. Off. Agric. Chem.*, 1953, **36**, 1077-1083. [Dept. Health, Washington 25, D.C.]

Cream, 20 g. or butter, 10 g., is shaken with ice-water and filtered through a special filter sieve. The collected fat is then washed with water and dissolved in ether and the ethereal solution is titrated against 0.05 N Na ethylate with phenolphthalein as indicator. For calculation purposes the mean molecular weight of water-insoluble acid is taken as 270. The estimation takes about 15 min.—G. A. Garton.

2755

MERTENS, E. and ALBERS, C. Über eine Modifikation der Cholesterinbestimmung im Blutserum nach Schönheimer und Sperry. [A modification of the Schoenheimer and Sperry

N.A. and R., July 1954

method for estimating cholesterol in blood serum.] *Hoppe-Seyler's Ztschr.*, 1953, **293**, 244-253. [Med. Abt., Marienkrankenhaus, Hamburg.]

Methods for the estimation of cholesterol are reviewed; that of Schoenheimer and Sperry (Title, p. 463, Vol. 4) was chosen as most suitable. A modified procedure is described, which is claimed to be more reliable than the original.—H. G. Bray.

2756

BROWN, H. H., ZLATKIS, A., ZAK, B. and BOYLE, A. J. **Rapid procedure for determination of free serum cholesterol.** *Anal. Chem.*, 1954, **26**, 397-399. [Dept. Pathol., Coll. Med., Wayne Univ., Detroit, Mich.]

Two procedures are described. In the first, aluminium hydroxide is used as a "gathering agent" for the precipitate of cholesteryl digitonide; this is isolated and dissolved in acetic acid and the cholesterol present is estimated by means of the ferric chloride colour reagent of Zlatkis *et al.* (Abst. 3890, Vol. 23). In the second procedure, aluminium chloride is used to flocculate the digitonide, which is then isolated by centrifuging and treated as in the first procedure.—H. G. Bray.

2757

HUENNEKENS, F. M., HANAHAN, D. J. and UZIEL, M. **Paper chromatography of lecithins.** *J. Biol. Chem.*, 1954, **206**, 443-447. [Dept. Biochem., Univ. Washington, Seattle.]

Paper chromatography was used for the separation of a series of compounds derived from the unsaturated lecithin (dipalmitoleyl)-L- α -glycerylphosphorylcholine. With different solvent systems (*n*-butanol saturated with water, ethanol-water, *n*-propanol-water and *n*-propanol-acetic acid-water) the following compounds were separated and identified: the parent unsaturated lecithin, saturated lecithin, unsaturated lysolecithin, saturated lysolecithin, α -monopalmitin, $\alpha\beta$ -dipalmitolein, phosphatidic acid, oleic acid, glycerylphosphorylcholine, β -glycerophosphate, phosphorylcholine and choline. Spray reagents were used to detect phosphate, choline ester linkages and unsaturated groupings.—G. A. Garton.

Vol. 24, No. 3

method for the determination of free choline in plasma. *J. Biol. Chem.*, 1953, **205**, 803-813. [Res. Serv., Third (New York Univ.) Med. Div., Goldwater Mem. Hosp., New York.]

The method consists in extraction of the choline into acetone, evaporation of the acetone and removal of interfering substances from the aqueous phase by extraction first with *n*-butanol and then with isobutanol, each alcohol being saturated with 2 *N* HCl. The choline is precipitated as its periodide, containing 9 atoms I per mol., and estimated spectrophotometrically by measuring the optical density at 365 $m\mu$. This method avoids washing the precipitate, as I adsorbed on the periodide precipitate does not interfere in the measurement. Counter-current distribution and partition studies have shown the method to be specific for plasma choline, and as little as 5 μ g. can be estimated. The method does not appear to be applicable to urine or to homogenised organ tissues.

In 21 healthy adult men the values for choline in plasma ranged from 2.5 to 9.9 μ g. per ml., average 4.4. The values remained relatively constant over several months and were not increased after meals or by the oral administration of 5 g. choline as the bicarbonate salt.—W. Godden.

DAVIDSON, J. **Procedures for the extraction, separation and estimation of the major fat-soluble pigments of hay.** *J. Sci. Food Agric.*, 1954, **5**, 1-7. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

The comminuted hay is moistened with water, deep frozen and thawed to rupture cell membranes, and mechanically blended with the solvent and the pigments are extracted with 85 per cent.

aqueous acetone. After the addition of magnesium oxide the pigments are transferred to ether. This solvent is then removed by evaporation and the residue is dissolved in light petroleum. With a column of equal parts of sugar and anhydrous sodium sulphate the pigments are separated with a green solution containing chlorophylls *a* and *b* and a yellow solution containing phaeophytins *a* and *b*, carotene and xanthophyll. The chlorophylls are estimated spectrophotometrically in the green solution and the phaeophytins in the yellow solution, measurements being taken in the red region of the spectrum. From the yellow solution carotene and xanthophyll are separated chromatographically on a magnesium oxide column and estimated separately. Five samples of hay gave the following ranges of values, expressed as mg. per 100 g. dry matter: chlorophyll *a* 55 to 64; chlorophyll *b* 34 to 42; phaeophytin *a* 6 to 12; phaeophytin *b* 1 to 3; carotene 0.4 to 1.1; xanthophyll 2.6 to 4.2.—W. Godden.

The method of Mason (Abst. 1292, Vol. 23) has been adapted for work on a micro-scale, the end-point being estimated by following photometrically the changes in optical density at $520 \text{ m}\mu$. The accuracy is ± 2 per cent. and the estimation is

completed in 10 min. A series of estimations should be checked against the results obtained with a standard solution containing 0.1 g. Ca per litre.—W. Godden.

2767

HÜBENER, H. J., MAURER, H. and WALTHER, T. **Eine einfache Differenzmethode zur genauen flammenphotometrischen Serum - Calcium-Bestimmung. [A simple difference method for accurate estimation of calcium in serum with the flame photometer.]** *Klin. Wochenschr.*, 1953, **31**, 1095-1096. [Inst. Veg. Physiol., Frankfurt a.M.]

Estimation of Ca in serum with the flame photometer suffers in accuracy from variations in the composition of the serum. To achieve greater accuracy it is suggested that a small amount of CaCl_2 be added to the serum, and that readings be taken of the serum with and without the added CaCl_2 , and of the CaCl_2 solution alone.

E. M. Hume.

2768

KIMBEL, K. H. **Zur Komplexon-Titration des Calciums im Serum. [On Komplexon titration of calcium in serum.]** *Hoppe-Seyler's Ztschr.*, 1953, **293**, 273-277. [Med. Poliklin., Univ. Würzburg.]

The method is considered from the point of view of its applicability to clinical investigations: suitable conditions are described. The dependence of the reaction on pH, precipitation conditions and the estimation of the end-point are considered in detail.—H. G. Bray.

2769

WARK, W. J. **Spectrographic analysis of minor elements extracted from plants and soils as dithizonates.** *Anal. Chem.*, 1954, **26**, 203-205. [Dept. Chem., Ontario Agric. Coll., Guelph.]

Cu, Co and Zn are extracted from ashed material as dithizone complexes. The recommended spectrographic procedure is described in detail.

H. G. Bray.

2770

HENNIG, K. and BURKHARDT, R. **Die quantitative, polarographische Bestimmung von Kupfer und Zink in der Weinasche. [Quantitative polarographic estimation of copper and zinc in ash of wine.]** *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1954, **98**, 25-29. [Inst. Biochem., Geisenheim am Rhein.]

By the polarographic method described, Cu and Zn can be estimated quantitatively in the ash of 100 ml. wine. The method involves little expenditure of chemicals and time and is thus suitable for serial estimations.—M. B. Richards.

N.A. and R., July 1954

2771

BINNERTS, W. T. **Determination of iodine in milk.** *Anal. chim. Acta*, 1954, **10**, 78-80. [Lab. Animal Physiol., Agric. University Coll., Wageningen, The Netherlands.] French and German summaries.

To 10 ml. of milk in Pyrex test tubes is added 1 ml. of a solution containing 2 per cent. NaOH and 1 per cent. KNO₃. Two periods of several hours' combustion at 550°C., during which another 1 ml. of the hydroxide-nitrate solution is added, are sufficient to give a white ash. A white-ash end-point is the criterion rather than a fixed time of heating. The ash is extracted several times with warm slightly alkaline water and filtered through Jena glass filters into 12-ml. Pyrex tubes. From this 10 ml. solution 1 ml. is used for photometry. The rate of disappearance of the yellow colour in the reaction between ceric sulphate and arsenious acid is a measure of the amount of iodine present. Two extinction readings with a 15-min. interval are taken. The reaction temperature is 30°C., but sensitivity to temperature change is very low.—B. W. Simpson.

2772

HÄBERLI, E. Eine Methode zur titrimetrischen Bestimmung des Eisens im Blut mit Hilfe von Komplexon. [A new method for titrimetric estimation of iron in blood by the use of Komplexon.] *Experientia*, 1954, **10**, 34-35. English summary.

A procedure is described for the volumetric estimation of total iron in blood using "Komplexon III" with catechol-3:5-disulphonic acid ("Tiron") as indicator. The method is not sensitive enough to be used for the estimation of serum Fe.—H. G. Bray.

2773

VENTURA, S. and WHITE, J. C. **The determination of iron and copper in single serum samples.** *Analyst*, 1954, **79**, 39-42. [Postgrad. Med. Sch., Ducane Rd., London, W.12.]

Four ml. serum is treated with 6 N HCl to liberate the metallic ions and deproteinised with trichloroacetic acid, and Fe and Cu in the filtrate are estimated with 2:2'-dipyridyl and sodium diethyldithiocarbamate, respectively. The dipyridyl colour is first developed and then the copper diethyldithiocarbamate complex is formed and extracted with ether and amyl alcohol, and the optical density of the 2 phases is measured.

BERNSTEIN, R. E. **Serum and plasma preparation for potassium analysis: effects of anticoagulants, storage time and temperature before separation, and haemolysis.** *S. African J. Med. Sci.*, 1953, **18**, 99-104. [Dept. Physiol., Med. Sch., Univ. Witwatersrand, Johannesburg.]

Owing to exchanges of K between red cells and serum or plasma heparinised blood is to be preferred to clotted blood for K estimations. Inorganic salt anticoagulants are unsuitable. For accurate results heparinised blood should be centrifuged immediately after collection, but blood samples, heparinised or allowed to clot, kept at room temperature and separated at a fixed time within 1 to 6 hr. after collection will yield comparable results. After a longer interval there is a progressive increase in the K value.

W. Godden.

2784

PIEN, J., DÉSRANT, J. and LEFÈVRE, B. **La recherche de la margarine dans les beurres. [Detection of margarine in butter.]** *Lait*, 1954, **34**, 11-22.

In 1931 an order was made compelling all manufacturers of margarine to incorporate 2 g. potato or rice starch per kg. in their product. In 1932 a

technique was published for the detection of starch in butter and hence of the adulteration of butter with margarine. Recently samples of butter, free from margarine, have been found to contain traces of starches of different kinds. A method is now described in detail for isolating, by a series of treatments with fat solvents and centrifuging followed by a series of washings first with dilute ammonia and centrifuging and finally with dilute HCl and centrifuging, the starch grains free from fat and casein. These can be counted in a haemocytometer or treated with Lugol's solution and the colour measured. If the total number of potato starch grains is less than 100,000 margarine is not present or at most in amount less than 1 per cent. in the butter. If no colour is detected with the iodine solution, less than 0.1 per cent. is present.

W. Godden.

VAZQUEZ, O. N., NEWERLY, K., YALO, R. S. and BERSON, S. A. Estimation of trapped plasma with I^{131} albumin; critique of methods. *J. Appl. Physiol.*, 1954, **6**, 437-440. [Radioisotope Unit, Vet. Admin. Hosp., Bronx, N.Y.]

It is concluded that errors in haematocrit measurements due to trapped plasma should be studied by means of materials which do not penetrate the erythrocyte. Under the conditions used in this investigation the error was estimated to be less than 2 per cent.—H. G. Bray.

2792

NYLIN, G. Circulatory studies with radio-active isotopes. *Acta med. scand.*, 1954, **147**, 275-298. [Stockholm.]

This is an account of 10 years' work in the development and use of techniques for labelling red blood cells with ^{32}P or radio-active thorium B. With a very small amount of activity, about 0.03 mC. ^{32}P , labelled blood cells lose only 2 or 3 per cent. of their activity in an hour although plasma activity declines more rapidly. This permits more accurate estimation of blood volume than is possible with T-1824. With thorium B the red cells remain constantly labelled for from 1 to 2 hr.

The techniques have been applied to the study of a number of problems concerned with circulation and mixing of blood in normal subjects and in patients with heart disorders.—D. Duncan.

2793

HEVESY, G. and NYLIN, G. Application of "Thorium B" labeled red corpuscles in blood volume studies. *Circulation Res.*, 1953,

Vol. 24, No. 3

1, 102-111. [Cardiovascular Clin., Södersjukhus, Stockholm.]

Thorium B is a satisfactory isotope for labelling red blood cells; the activity of re-injected labelled cells remains almost constant for at least an hour and decays by only one-third to one-quarter in 24 hr. About 99 per cent. accumulates in the red corpuscles. The method described is simple, requiring no centrifuging of blood samples and no calculation of cell: plasma ratios.—D. Duncan.

SPEERBER, I., HYDÉN, S. and EKMAN, J. **The use of polyethylene glycol as a reference substance in the study of ruminant digestion.** *Kgl. Lantbrukshögsk. Ann.*, 1953, **20**, 337-344. [Inst. Animal Physiol.]

Polyethylene glycol is not adsorbed or destroyed to any measurable extent in the rumen contents, and 90 per cent. or more can be recovered in the faeces. There was no evidence of its absorption, as none appeared in the urine after oral administration although it was soon detected in the urine after injection of small quantities into the blood. It appears that it can be used to estimate the flow of digesta from the reticulo-omasal orifice and to assess the flow of water and of dissolved substances from the rumen. An example of its use is given, and the conclusions drawn agree fairly satisfactorily with other relevant data.—A. T. Phillipson.

2809

MICHAEL, S. J. and MCKINLEY, R. E. **Rumeno-tomy simplified.** *J. Amer. Vet. Med. Assoc.*, 1954, **124**, 26-27. [Erie, Pa.]

A simple rumen retractor enables rumenotomy to be performed without assistance, and at the same time gives added protection against contamination of the wound.

The instrument consists of an aluminium ring with a slightly smaller rubber ring attached to its inner circumference. This double ring is suspended by a web strap attached to the skin on the right side of the animal by a spring clip. To the rubber ring is attached a series of sharp-pointed hooks, which can be inserted into the margins of the incision in the rumen; these can then be withdrawn from the abdominal cavity and lapped 1 to 2 in. over the margins of the skin incision.

KROC, R. L., PHILLIPS, G. E., STASILLI, N. R. and MALAMENT, S. **Antigoitrogenic and calorogenic assay of thyroglobulin, desiccated thyroid and l-thyroxine by different routes of administration in rats.** *J. Clin. Endocrinol.*, 1954, **14**, 56-69. [Res. Div., Warner-Chilcott Labs., Morris Plains, N.J.]

Two methods of bio-assay were used, anti-goitrogenic and calorogenic, to compare the activity of thyroglobulin with that of l-thyroxine sodium pentahydrate. The activities of 3 commercial products were ascertained at the same time. Different routes of administration were also compared. Assigning the value 100 to the activity of l-thyroxine administered subcutaneously, the anti-goitrogenic and calorogenic activities of thyroglobulin were 349 and 345, respectively. When they were given by mouth the activities of thyro-

globulin were 183 and 88 and those of l-thyroxine 34 and 26 by the anti-goitrogenic and calorogenic methods, respectively. The 2 methods gave results in fairly good agreement for the relative potencies of l-thyroxine sodium and soluble thyroglobulin administered as solutions subcutaneously or by mouth, but gave different results for the activities of the commercial products. The anti-goitrogenic assays of these gave values three times as high as those by the calorogenic assays. The method of assay of commercial products should, therefore, be stated. Soluble thyroglobulin was equally active whether administered intravenously, intraperitoneally or subcutaneously. The rate of absorption did not explain the fact that the activity of thyroglobulin was greater than could be accounted for by its thyroxine iodine content.

2815

ERIKSSON, S. **Accuracy in determining digestibility of poultry feeds.** *Kgl. Lantbrukshögsk. Ann.*, 1953, **20**, 7-18. [Inst. Animal Nutrit.]

A comparison of direct and indirect methods of estimating the digestibility of poultry feeds was made with hens fed individually. Indirect estimations were made with chromic oxide, either 1.5

g. given daily or 1 per cent. mixed with the feed. In 2 series of experiments controlled daily feed intake with 6-day collection periods was compared with feeding to appetite and 2-day collection periods. The average digestion coefficients of the proximate nutrients were the same for both direct and indirect estimations and for the 2 methods of feeding. The indirect method was less reliable than the direct method with feeding to appetite.

MAL'CHEVSKII, A. S. and KADOCHNIKOV, N. P. Metodika prizhiznennogo izucheniya pitaniya gnezhdovykh ptentzov nasekomoyadnykh ptitz. [Methods in the contemporary study of the nutrition of fledgelings of insectivorous birds.]

Zool. Zh., 1953, 32, 277-282. [Leningrad Gosud. Univ.]

The method consists in applying a ligature of suitable material to the neck of the fledgeling in such a way as to prevent swallowing without inhibiting respiration. After a given period of feeding by the parents, the material is easily extracted from the oesophagus with forceps and analysed. The length of time for which such an experiment can be permitted, and the conditions of observation generally, depend on the species. Subject to safeguards, the fledgelings do not appear to suffer, and the method is contrasted with the waste and destruction when gastric analysis is employed. Results are described for a large number of species.—D. W. Taylor.

SELESTE, E. The keeping quality of cow's milk and mother's milk. Investigations with reference to temperature, heat treatment, changes in flavour and pH, and the lysozyme content. *Ann. Med. exp. Biol. Fenn.*, 1953, 31, Suppl. 8, pp. 78. [Child. Clin., Univ. Helsinki.]

The literature is reviewed. Experiments were made on the effects of storage temperature and methods of pasteurisation on cow's milk and breast milk. The latter retained its flavour and pH well for short periods, up to 5 days, at 18°, 20°, or even 37° C., but did not keep well in the refrigerator at 4° C. The reverse was found with cow's milk. After inoculation with *Streptococcus lactis* breast milk retained flavour and pH more satisfactorily at 18° or 20° C. than in the refrigerator. There was no correlation between flavour and pH in milk, and pH variations were not a reliable guide to quality.

Pasteurisation for a short time at high temperature was more satisfactory for cow's milk and by the holder method at lower temperature for breast milk. The lysozyme activity of breast milk was high and that of cow's milk very low. Lysozyme activity was retained in breast milk after pasteurisation. Lysozyme activity was probably partly responsible for the keeping quality of good samples of breast milk.—A. M. Copping.

PATTON, S., KEENEY, P. G. and HERALD, C. T. The role of lactones in flavour deterioration of milk fat. *Science*, 1954, 119, 218-219. [Pennsylvania Agric. Exp. Stat., State College.]

There are indications that the coconut-like off-flavour developed by milk fat during storage may be due to the presence of δ -decalactone. Storage

in vacuum or inert gas will not prevent its occurrence; the only method so far found satisfactory is to keep it at low temperature, 0° C. or below. These preliminary findings, while not excluding an effect of minute amounts of oxygen, suggest that non-oxidative rearrangement of unsaturated fatty acids to lactones may be the cause.—D. Harvey.

EL-SOKKARY, A. M. and ZAKI, M. H. Stability of buffalo, cow, sheep and goat samna (ghee) against oxidative deterioration. *Indian J. Dairy Sci.*, 1953, 6, 217-221. [Fac. Agric., Ibrahim Univ., Shebin El-Kom, Egypt.]

There was little difference in the composition of samna prepared from buffalo, cow, ewe or goat milk. A typical analysis (buffalo samna) was: water 0.34, fat 99.34, solids-not-fat 0.34 per cent.

Samples were held at 78° C. and peroxide values were estimated at 24-hr. intervals. The periods elapsing before a peroxide value of 5 was reached were: buffalo 146, cow 176, ewe 149, goat 218 hr. The comparatively high stability of goat samna may be due to the presence of fat-soluble anti-oxidants.—P. C. Jowsey.

TAPPEL, A. L. **Oxidative fat rancidity in food products. 1. Linoleate oxidation catalyzed by hemin, hemoglobin, and cytochrome c.** *Food Res.*, 1953, **18**, 560-573. [Dept. Food Technol., Univ. California, Davis.]

Haemin, Hb and cytochrome c were found to be relatively powerful as catalysts of the oxidation of linoleate at 0° C. and, except for lipoxidase (see Title 2743, Vol. 23), appeared to be the most active of naturally-occurring oxidising catalysts. The oxidation of pork fat was attributable to its haematin content rather than to a simple process of auto-oxidation. The activation energy of linoleate oxidation catalysed by haematin compounds was found to be low compared with that of auto-catalytic linoleate oxidation, which may explain the need for exclusion of O₂ or the addition of anti-oxidants or both if a reasonable storage life is to be attained at conventional temperatures for freezing such foods as pork, fish and poultry.

In concentrations 2×10^{-3} M α -tocopherol *nordihydroguaiaretic* acid and propyl gallate were effective in inhibiting haemin-catalysed oxidation when they were initially present, but such a concentration did not stop oxidation once started. During linoleate oxidation in the presence of haemin the enzyme was co-oxidised and Fe was released.—D. Harvey.

HARTMAN, L. and WHITE, M. D. L. **Stability of edible tallow from mutton and beef. 2. Suppression of the deleterious effect of trace metals.** *N.Z. J. Sci. Technol. [B]*, 1953, **35**, 254-258. [Fats Res. Lab., Dept. Sci. Indust. Res., Wellington.]

For Part 1 see Abst. 2742, Vol. 23.

Two procedures for removing Cu and Fe from edible tallow and the effects of 5 de-activators, citric, tartaric, citraconic and gluconic acids and commercial ethylenediamine tetra-acetic acid, were tested. There was no correlation between Fe content and stability and the amount of Cu was too small to justify a similar conclusion. Citric and tartaric acids were the most effective of the de-activators, but their use in New Zealand is prohibited by food regulations.—D. Harvey.

KANTHARAJ URS, M., SAHASRABUDHE, M. R., BHATIA, D. S. and NATARAJAN, C. P. **Studies on the storage behaviour of mustard and groundnut oils in galvanized iron containers.** *Bull. Central Food Technol. Res. Inst., Mysore*, 1953, **3**, 17-18.

Fresh, peroxide-free samples of mustard oil and of crude and refined groundnut oils were stored in glass, tin and galvanised iron containers of capacity

Vol. 24, No. 3

4 oz. Peroxide and acid values were estimated at intervals during 36 weeks' storage at room temperature, 37° or 50° C.

At 37° C. the acidity of oils stored in tin or glass increased over 36 weeks; in galvanised cans the acidity was neutralised to some extent by Zn dissolved from the surface of the container. All the oils at all temperatures dissolved Zn; the amount ranged from 32 p.p.m. for refined groundnut oil stored at room temperature to 1228 p.p.m. for crude groundnut oil stored at 50° C. In general, the higher the storage temperature, the greater the amount dissolved.

It was concluded that mustard oil, which is never refined, and crude groundnut oil should not be stored in galvanised containers.—P. C. Jowsey.

WANG, H., AUERBACH, E., BATES, V., ANDREWS, F., DOTY, D. M. and KRAYBILL, H. R. **A histological and histochemical study of beef dehydration. 2. Influence of carcass grade, aging, muscle and electrolysis pre-treatment.** *Food Res.*, 1954, **19**, 154-161. [Amer. Meat Inst. Found., Univ. Chicago, Ill.]

For part 1 see Abst. 176, Vol. 24.

Cylindrical portions of 2 muscles, *Rectus femoris* and *Biceps femoris*, were taken from beef carcasses of 4 grades of quality when fresh and after

storage for 7 or 14 days. One set of samples underwent electrolysis before dehydration at 70° C.; a control set was not electrolysed before treatment. All were subsequently rehydrated. Neither grade of carcass nor length of ageing period influenced dehydration or rehydration.

During electrolysis potassium was lost from and water was taken up by the tissue. Rehydration was much more rapid and complete by the electrolysed than by the non-electrolysed samples.

LERCHE, M. Die Bedeutung des Ausruhens der Schlachttiere für die Fleischwarenqualität. [Importance of resting animals before slaughter for the quality of meat products.] *Berl. Münch. tierärztl. Wochenschr.*, 1954, **67**, 40-43. [Inst. Lebensmittelhyg., Freie Univ. Berlin.] English summary.

Unsatisfactory canned ham was traced to the use of soft, insufficiently bled meat from pigs which had been transported for long distances and not properly rested before slaughter. After curing and before canning, such hams often showed poor appearance, consistency and odour, and the pH tended to be higher than that of hams from properly slaughtered pigs, though poor quality and high pH did not always go together. Careful investigation of the period of rest required is called for.—W. M. Deans.

PINGALE, S. V., NARAYANA RAO, M. and SWAMINATHAN, M. **Effect of insect infestation on stored grain. 1. Studies on soft wheat.** *J. Sci. Food Agric.*, 1954, **5**, 51-54. [Central Food Technol. Res. Inst., Mysore, India.]

Soft wheat in 70-lb. lots in closely woven bamboo bins was infested with 100 adults of *Calandria oryzae*, L. (weevil), *Trogoderma granaria*, E. (khapra beetle) and *Ephestia cautella*, W. (almond moth) and kept for 6 months at temperatures between 78° and 84° F. and humidities between 48 and 62 per cent. Samples were examined monthly and N, moisture, ash, fat, fat acidity and reducing sugars were estimated by A.O.A.C. methods and vitamin B₁ by Swaminathan's modification of the thiochrome method (Abst. 2033, Vol. 12).

Weight loss was considerable, especially with weevils. There was little effect on percentage total N or reducing sugars; the rise in fat acidity was greater in infested samples than in controls, but there was no off-flavour. About half the initial vitamin B₁ content of 4.5 µg. per g. was lost after 3 months; the worst loss was with *Ephestia*, which eats the germ only. This is serious in countries such as India, where the people live largely on cereals.—W. M. Deans.

HOLMES, A. D., SPELMAN, A. F. and WETHERBEE, R. T. **Effect of storage on butternut squash and its seeds.** *J. Amer. Dietetic Assoc.*, 1954, **30**, 138-141. [Massachusetts Agric. Exp. Stat., Amherst.]

Sixty mature and 60 immature squashes (*Cucurbita moschata*, Duchesne) were stored in the dark for 221 days at an average temperature of 60° F., range 54° to 70° F., and average relative humidity 76 per cent., range 70 to 90 per cent. Water,

N.A. and R., July 1954

protein, fat, total sugars, starch and carotene were estimated in the edible parts and the seeds on 6 occasions during storage.

Water and protein in the edible parts of both mature and immature squashes remained fairly constant; total sugars and carotene increased and starch decreased during storage. In the seeds, water, total sugars, starch and carotene decreased and protein tended to increase, particularly in immature samples.

The seeds contained about 5 times as much protein as did the edible parts of the same squashes with, in addition, from 31 to 34 per cent. fat, on a dry matter basis.—P. C. Jowsey.

2837

PRUTHI, J. S., TANDON, G. L. and SIDDAPPA, G. S.
Removal of hydrocyanic acid from tender bamboo shoots. *Bull. Central Food Technol. Res. Inst., Mysore*, 1953, **3**, 41–42.

The conventional method of removing HCN from tender bamboo shoots used for food is to soak them in cold water for 18 to 24 hr. This method is not completely effective nor is soaking in brine for 2 hr. Complete removal is attained by steaming for 1 hr. with one change of water.

J. S. Thomson.

2838

DESCHREIDER, A. R. Étude sur la cuisson des aliments dans des ustensiles de cuisine en aluminium. [**Cooking food in aluminium utensils.**] *Chimia*, 1953, **7**, 248–255. [Lab. Central, Minist. Affaires Econ., Brussels.]

Trials with different types of aluminium cooking utensils showed that the amount of Al entering into solution in boiling solutions of NaCl, NaHCO₃, Na₂CO₃ or weak acetic acid depended upon the nature of the salt and the quality of the vessel and amounted in some cases to 20 p.p.m.

When foods including milk were boiled in such vessels the amount of Al entering the food was, with the exception of rhubarb, generally less than that already present in the food. It is considered that care should be taken in the use of aluminium cooking vessels and also in the use of baking powder known to contain Al salts.—D. Harvey.

DUFOUR, L., NIEDERMEIER, R. P., ZEHNER, C. E. and CROWLEY, J. W. **Sulfur dioxide as a preservative for high moisture legume silage.** *J. Dairy Sci.*, 1954, **37**, 52–57. [Dept. Dairy Husb., Univ. Wisconsin, Madison.]

Alfalfa and red clover forage was ensiled with or without SO₂ at a rate of 5.66 lb. per ton in 2 silos holding about 24 tons each. About 6½ months later the silos were opened and the contents were given to 2 groups each of 8 cows. Silage from different depths in the silos was analysed for proximate constituents and carotene.

Both silages were palatable and daily consumption was on the average 65 lb. per cow. Both groups gained weight at similar rates and milk production was similar. The SO₂-treated silage was of significantly lower pH, moisture and fibre and higher in protein than untreated silage. No significant difference between silages was shown for ether extract, ash and carotene.—P. C. Jowsey.

2844

REISER, C. O. **Food yeast. Torula yeast from potato starch wastes.** *J. Agric. Food Chem.*, 1954, **2**, 70–74. [Dept. Chem. Eng., Univ. Idaho, Moscow.]

A 30-litre laboratory fermenter, which is illustrated, was used to produce food yeast by propagation of *Torulopsis utilis* in waste liquor from a potato starch extraction plant. Batch production

with 10 litres of medium resulted in a solids recovery rate of 45 per cent. Continuous production in which 2.5 litres per hr. were removed and replaced resulted in a solids recovery of over 45 per cent. Full technical details are given.

Larger scale propagations were made with 40-gal. batches of medium in an 80-gal. stainless steel kettle. Solids recovery averaged 40 per cent.

Preliminary designs and flow diagram for a commercial plant are described and costed. A 30-ton starch plant could produce 4.5 tons of yeast daily at a cost of about 5 cents per lb., with a preliminary investment of \$165,000.

The yeast had a protein content of about 55 per cent. and preliminary feeding trials with chicks showed it to have a feeding value equivalent to a mixture of fish, meat and soya bean meals.

P. C. Jowsey.

FOODSTUFFS OF ANIMAL ORIGIN

Milk and Milk Products

2850

HYTTEN, F. E. Clinical and chemical studies in human lactation. 1. Collection of milk samples. 2. Variation in major constituents during a feeding. 3. Diurnal variation in major constituents of milk. 4. Trends in milk composition during course of lactation. 5. Individual differences in composition of milk. *Brit. Med. J.*, 1954, i, 175-176; 176-179; 179-182; 249-253; 253-255. [Dept. Midwifery, Univ. Aberdeen.]

1. In 83 subjects, 7th-day yield of milk obtained by manual expression was less than 6th-day yield obtained by weighing infants and measuring residual milk obtained by manual expression after feeds. In 85 subjects 7th-day yield obtained with the "humalactor" breast pump exceeded 6th-day yield computed from test weighings and measured strippings.

These results suggested that manual expression decreased milk secretion. For this reason and also because of the convenience of mechanical expression in obtaining 24-hr. milk output, the humalactor was used in subsequent studies of milk yield and composition.

2. Consecutive samples of milk obtained during the emptying of a breast in several subjects were analysed for fat, lactose and N. There was a progressive and usually large increase in fat content with a small decrease in lactose. Total N fell from the beginning to the end of the sampling

N.A. and R., July 1954

during the first few days of lactation, but in later milk there was usually a small increase as the breast was emptied.

It is suggested that the behaviour of the fat is due to adsorption of the fat globules on the large secretory and duct surface of the breast. This view was supported by analysis of samples of milk progressively expressed by compression of a rubber sponge soaked in human milk.

3. Forty-nine 24-hr. samples were collected from 42 women at the usual feeding times of 6 and 10 a.m., 2, 6 and 10 p.m. The yield and composition of milk from women on the 21st day *post partum* and later are shown separately from those results relating to earlier milk.

In both series, yield at 6 a.m. was significantly greater than at other times. In the earlier milk, yield at 10 p.m. was significantly lower than at other times. In both series fat content was lowest at 6 a.m. and highest at 10 a.m. The mean diurnal variation in fat output presented graphically shows that total daily fat output cannot be assessed accurately from the analysis of any single sample.

Possible factors governing the volume of milk obtained at a feeding are considered.

4. Fat, lactose, total N and N.P.N. were estimated in 240 24-hr. samples of milk collected at different stages of lactation from 194 women. Individual variation in milk output was very great. Yield rose rapidly during the first week and then more slowly. Total N and N.P.N., initially high, fell steeply during the first 3 days and then more slowly until the second month or later. Lactose content rose from an initially low level to a stable level within the first month of lactation. Fat content, usually low during the first few days, rose slowly up to the second month. Analyses of serial samples of milk from 4 women indicated that the range of values of lactose and N diminishes after the seventh day, but individual differences in fat content on the 7th day are maintained. Seventh-day fat is, therefore, a good indication of the fat content of mature milk in each individual.

The doubtful significance of the term colostrum is discussed.

5. The results of the analysis of 150 samples of 7th-day milk presented in part 4 were used in this study. There was no statistically significant difference in average volume and composition of milk between 121 primiparae and 29 multiparae. For 6 of the multiparae, volume and fat content of milk in a previous lactation were known. These results showed that the same individual in two lactations may produce milks of widely different fat content.

Statistical analysis of data relating to the 121 primiparae indicate that there is a physiological

upper limit to lactose content and a lower limit to protein content. Lactose tends to be positively related and protein to be negatively related to milk volume. Fat content is independent of all three, and in some milks the fat content is so low that even with a high milk volume energy intake of the infant would be insufficient.

The variability of lactose and protein content is attributed to differences in speed of maturation of the milk. The reason for the wide individual differences in fat content is at present obscure.

F. C. Aitken.

SOUPART, P., MOORE, S. and BIGWOOD, E. J.

Amino acid composition of human milk. *J.*

Biol. Chem., 1954, **206**, 699-704. [Dept.

Biochem. Nutrit., Fac. Med., Univ. Brussels.]

Two samples of pooled milk, collected from 20 and 40 mothers, respectively, in the urban district of Brussels were hydrolysed with acid and the hydrolysate was analysed by ion exchange chromatography on Dowex 50. Tryptophan was estimated microbiologically in an alkaline hydrolysate. The results for 18 amino-acids are expressed as mg. per 100 ml. milk and these, with ammonia, account for 88 per cent. of the total N.—W. Godden.

2852

JANSE, L. C. **The composition of Friesian milk.** 2.

Nederlands Melk Zuiveltijdschr., 1953, **7**, 199-

203. [Lab. "Federation of Co-operative

Dairies in Friesland", Leeuwarden.] Dutch

summary.

Fat, solids-not-fat, total protein, casein and lactose were estimated by methods previously described (Abst. 3261, Vol. 20) in 3258 samples of milk collected during 1952-53.

The results are presented as regression lines for fat/solids-not-fat, fat/total protein, fat/lactose and fat/casein.

With an increase in fat content from 2.7 to 5.7 per cent., the following were correlated: total protein increased by 1.1 per cent., solids-not-fat and casein each increased by 0.9 per cent. and lactose decreased by 0.3 per cent.—P. C. Jowsey.

WHITTLESTONE, W. G. **The physical properties of**

cow's milk as influenced by stage of lactation.

The size distribution of butterfat globules. *J. Dairy Res.*, 1954, **21**, 50-54. [Ruakura Animal Res. Stat., N.Z. Dept. Agric.]

With the method previously devised for cows (Abst. 1714, Vol. 22), samples of milk drawn sequentially by machine from one quarter of one cow's udder were examined at different stages in a lactation. There was no obvious trend in the size of fat globules as between middle milk and strippings, as between morning and evening milks, or with stage of lactation. The increase in the fat content of strippings cannot be explained as due to the filtering out of large globules or to creaming effects due to the rise of large globules.—W. Godden.

2855

VAN MIDDLESWORTH, L., TUTTLE, A. H. and THRELKELD, A. **Iodinated protein in milk.** *Science*, 1953, **118**, 749. [Dept. Physiol., Univ. Tennessee, Memphis.]

Samples of milk collected 4 and 24 hr. after the injection of 2.5 or 8 mC. of ^{131}I into 2 lactating bitches were analysed and studied by paper electrophoresis. The non-dialysable ^{131}I was associated mainly with the slow-moving protein but was present in all protein fractions separated. After hydrolysis the presence of 2 radio-active substances was demonstrated chromatographically.

From these findings and those of earlier work (Abst. 294, Vol. 22) it was concluded that milk contains an iodinated protein and that purified casein possesses a thyroid-like property of goitre prevention.—D. Harvey.

KHERASKOV, S. **Moloko verbludits i produkty ego pererabotki. [Camel's milk and products made from it.]** *Mol. Prom.*, 1953, **14**, No. 10, 36. [Chkalov S Sel'khoz. Inst.]

Camel's milk is white and contains more fat and lactose than cow's milk. The following values are given for camels with one and two humps, respectively: fat 4.47, 5.39 g. per 100 ml.; total protein 3.5, 3.8 per cent.; lactose 4.95, 5.2 per cent.; ash 0.70, 0.69 per cent.; acid number 15.5, 16.6; density 1.0305, 1.0320. Cheese made from camel's milk is solid but of floury consistency, and has a distinctive taste. Camel's milk is mixed with cow's or ewe's milk for making cheese which is highly prized in the Turkmenian and Kazakhstan republics. "Shubat", which resembles koumiss, is used as an appetiser and a remedy for tuberculosis and anaemia.—W. Hughes.

2861

JANKOWSKI, Z. **Badania nad składem chemicznym mleka owczego i zętycy. [Chemical composition of ewe's milk and whey.]** *Rocz. Państwowego Zakł. Hig.*, 1953, No. 4, 459-471. [Stac. Sanit.-Epidemiol., Zakopane.] Russian and French summaries.

Ewe's milk from the Jaworzynka valley was similar in composition to that reported from other European countries. Samples taken during the season showed a progressive rise in fat content.

Whey is consumed chiefly by shepherds and its nutritive value is high. The sugar and fat contents are about the same as those of milk but the nitrogen content is much lower. (From summary.) J. S. Thomson.

2862

PERRIN, D. R. **The composition of sow's milk during the course of lactation.** *J. Dairy Res.*, 1954, **21**, 55-62. [Ruakura Animal Res. Stat., N.Z. Dept. Agric.]

Milk from 44 sows, mostly Berkshires, sampled through 68 lactations was analysed at weekly intervals from the 7th day to the end of lactation and data for total solids, fat, solids-not-fat, protein, lactose and ash are presented in detail. The milk was obtained by machine-milking after intravenous injection of oxytocin.

Mean values for some constituents, based on the analysis of over 450 samples taken from the 7th to the 56th day of lactation were: fat 9.58, protein 6.11, lactose 4.62, ash 0.92 per cent., but the variation was great. Some data on day-to-day variations are given also.

In general fat rose for 3 weeks and fell steadily over the rest of the lactation. Protein fell rapidly in the first week from about 17 per cent. and then more slowly to about the 16th day. It then rose steadily to about 7 per cent. at the end of lactation. Lactose remained steady for 2 weeks, then fell slowly for the rest of the period. Total solids rose for 3 weeks and then fell slowly thereafter, and ash tended to rise steadily throughout lactation. For all constituents the 3rd week of lactation seemed to be a critical period when the trend was set for the remainder of the lactation.

P. C. Jowsey.

2863

PERRIN, D. R. **The estimation of the energy of sows' milk from fat and total solids content.** *J. Dairy Res.*, 1954, **21**, 63-66. [Ruakura Animal Res. Stat., N.Z. Dept. Agric.]

It has been shown (preceding Abst.) from a study of the chemical composition of the milk of 44 sows over 68 lactations that the ash and lactose content of sow's milk show well-defined trends during the course of a lactation and do not change significantly with varying dietary levels. With these data and applying Anderson's values (*Nord. Jordbrugsforsk.*, 1926, **4**, 133) for the energy value of fat, protein and lactose it is possible to calculate the energy value of sow's milk on an estimated composition requiring only the estimation of percentages of fat and total solids for its calculation.—W. Godden.

KOLOUŠEK, J. and MICHALÍK, S. **Studium aminokyselin v sýrech pomocí rozdělovací chromatografie na papíře. [Study of the amino-acids in cheese by means of paper partition chromatography.]** *Sborn. čsl. Akad. Zéměd.*, 1954, **27**, 67-78. [Lab. Agrobiochem., Vysocké Školy, Prague.] Russian and English summaries.

The free amino-acids of different cheeses differed both qualitatively and quantitatively; changes due to proteolysis occurred during the ripening of one particular type of cheese. The amino-acid composition of cheese protein did not change qualitatively during ripening.

Roquefort, Emmental and Moravian bochník cheeses contain all the essential amino-acids.

The paper chromatographic method of analysis described [in Czech] is recommended for the routine control of cheesemaking. (From summary.)

P. C. Jowsey.

2865

DACRE, J. C. **Amino-acids in New Zealand Cheddar cheese: their possible contribution to flavour.** *J. Sci. Food Agric.*, 1953, **4**, 604-608. [Dairy Res. Inst. (N.Z.), Palmerston North.]

Fifteen amino-acids were identified in the water-soluble N fraction of the cheese. The relative con-

centrations of the amino-acids were deduced by visual appraisal of the colours produced with ninhydrin on paper chromatograms prepared at intervals during the storage of the cheese up to 6 months.

All the amino-acids except tyrosine increased in amount as the cheese matured. Tyrosine concentration fluctuated, owing probably to the decarboxylating activity of the lactobacilli present in the cheese. No correlation between the time of appearance of a particular amino-acid and the development of Cheddar cheese flavour was apparent, nor did single or mixed amino-acids or their corresponding amines have any smell or taste resembling such a flavour.—P. C. Jowsey.

2866

OHTA, K., WATARAI, T., OISHI, T., UESHIBA, Y., HIROSE, S., YOSHIZAWA, T., AKIKUSA, Y., SATO, M. and OKANO, H. **Composition of fin whale milk.** *Proc. Japan Acad.*, 1953, **29**, 392-398. [Dept. Paediat., Dent. Med. Univ., Tokyo.]

Two samples of fin whale milk refrigerated for 2 and 13 months were examined. Both were viscous and creamy, with a flavour like cod liver oil. The solids amounted to 4 times those of human or cow's milk and the protein to 8 times that of human and 4 times that of cow's milk. The distribution of protein components and amino-acids resembled that in human milk. The fat content was over 30 per cent. and the fat globules were large. The lactose contents were 0.2 and 0.3 per cent. The Ca and P contents resembled those of cow's milk, and carotenoids, vitamin B₁ and riboflavin were present. The milks had high acidity, which may have been due to fatty decomposition during the long storage.—A. M. Copping.

Eggs

2867

MACDONNELL, L. R., DUCAY, E. D., SUGIHARA, T. F. and FEENEY, R. E. **Proteins of chicken, duck, and turkey egg white.** *Biochem. biophys. Acta*, 1954, **13**, 140-141. [W. Reg. Res. Lab., Bur. Agric. Indust. Chem., Albany, Calif.]

The white of eggs from chicken, turkey, Pekin duck and mallard contained, respectively: lysozyme 3.4, 1.84, 0.94, 0.86; conalbumin 12.0, 11.0, 2.8, 2.9; ovomucoid 11, 11, 15, 15; cysteine (in native protein) 0.46, 0.42, 0.32, 0.28; (in denatured protein) 0.62, 0.47, 0.37, 0.29 per cent. on a dry matter basis.—P. C. Jowsey.

Meat (all kinds)

SHEWAN, J. M. The nitrogenous extractives from fresh fish muscle. 2. Comparison of several gadoid and elasmobranch species. *J. Sci. Food Agric., 1953, 4, 565-568. [D.S.I.R., Torry Res. Stat., Aberdeen.]*

Aqueous-ethanolic extracts of muscle of 9 gadoids and 3 elasmobranchs caught in the North Sea were studied by the methods described in the first paper of this series (Abst. 194, Vol. 23).

Qualitative analysis showed the presence of 13 amino-acids and creatine, creatinine, trimethylamine oxide and possibly glutathione in all species examined. Betaine and sarcosine were found in elasmobranchs only; anserine and methylhistidine in gadoids only.

Samples from species within a group were closely similar, but there were wide differences between the 2 groups.—P. C. Jowsey.

AREVALO PADILLA, R. Estudio químico bromatológico de la carne del "*Acanthistius pictus*" o Cherlo. [Chemical and bromatological study of the flesh of *Acanthistius pictus*.] *An. Fac. Farm. Bioquim., Lima, 1952, 3, 160-163. [Lab. Bromatol., Univ. Lima.]*

The flesh of the fish *Acanthistius pictus* had the following percentage composition on a fresh basis: water 76.2, dry matter 23.8, protein 18.75, digestible protein 16.96, fat 3.06, carbohydrates 0.0052, total ash 1.53, Ca 0.131, Fe 0.0006, Cu 0.0004, P 0.114, Cl 0.16, Na, K and I traces, tyrosine 0.724, tryptophan 0.050. Vitamin A averaged 9250 I.U. per g. fat; the energy value was 103 Cal. per 100 g.

P. C. Jowsey.

2872

CASTILLO LA ROSA SANCHEZ, I. Estudio bromatológico de la carne de "*Anisotremus scapularis*" o "Chita". [Bromatological study of the flesh of *Anisotremus scapularis*, the sea bream.]

An. Fac. Farm. Bioquim., Lima, 1952, 3, 136-140. [Lab. Bromatol., Univ. Lima.]

The flesh had the following percentage composition on a dry matter basis: total protein 78.1, digestible protein 70.9, fat 16.5, total ash 5.0; vitamin A averaged 11,400 I.U. per g. fat; the energy value was 461 Cal. per 100 g. The following minerals were present: Ca 0.27, P 0.53, Fe 0.0029, Cl 0.31 g. per 100 g. dry matter, I a trace. Tyrosine and tryptophan amounted to 1.83 and 1.09 per cent., respectively.—P. C. Jowsey.

2873

COSTA SAENZ, F. Estudio bromatológico del "*Ethmidium chilcae*" o "Machete". [Bromatological study of *Ethmidium chilcae*.] *An. Fac. Farm. Bioquim., Lima, 1952, 3, 150-154. [Lab. Bromatol., Univ. Lima.]*

Analysis of the flesh of *Ethmidium chilcae* gave the following values per cent. in fresh material: moisture 72.08, fat 6.14, total protein 19.54, digestible protein 16.45, and total ash 1.442; Ca 0.186, P 0.103, Cl 0.056, Fe 0.003, traces of I and Cu; energy value 133 Cal. per 100 g. In the flesh there were 13,712 I.U. vitamin A, and in the liver 16,875 I.U. each per g. fat. Tyrosine formed 0.611 and tryptophan 0.149 per cent. of the total protein. This fish is recommended for consumption because of its abundance and low cost, and the biological value of its protein.—M. B. Richards.

2874

VALLEJOS PLANTANO, C. Análisis bromatológico de la carne de "*Paralanchurus peruanus*", "Coco" o "Suco". [Bromatological analysis of the flesh of *Paralanchurus peruanus*.] *An. Fac. Farm. Bioquim., Lima, 1952, 3, 155-159. [Lab. Bromatol., Univ. Lima.]*

Analysis of the flesh of *Paralanchurus peruanus* gave the following values, in g. per 100 g. fresh material: moisture 81.17, fat 1.40, total protein 15.76, digestible protein 12.06, total ash 1.19; Ca 0.109, P 0.209, Fe 0.0012, Cl 0.0852, I 0.0119, and traces of Cu; carbohydrates 0.0035; energy value 76 Cal. per 100 g.; vitamin A 7000 I.U. per g. fat; tyrosine 0.527 and tryptophan 0.085 g. per cent.—M. B. Richards.

2875

GARCIA TERRY, O. E. Valoración de los aminoácidos azufrados: cistina, cisteína y metionina en peces. [Estimation of sulphur amino-acids (cystine, cysteine and methionine) in fish.] *An. Fac. Farm. Bioquim., Lima, 1952, 3, 99-115. [Lab. Dept. Municip. Sanidad, Lima.]*

Methionine, cystine and cysteine were estimated in the protein of 3 species of fish: *Thunnus macropterus*, *Mustelus mento*, and *Ethmidium chilcae*. For 10 samples of each species, in the

N.A. and R., July 1954

above order, the averages, in g. per 100 g. pure protein, were: methionine 3.7, 3.6, 3.9; cystine 1.9, 1.8, 1.9; cysteine 0.44, 0.39, 0.47. The results are close to those given by Block and Bolling. The Sullivan and McCarthy method was used for the estimation of methionine, and the Folin technique as modified by Block and Bolling for cystine and cysteine. The work includes a study of some of the conditions which influence the hydrolysis and the colorimetric reactions.

M. B. Richards.

Other Types

2876

DE LA TORRE A., M.C. *Valuación de metionina, cistina y cisteína en algunos crustáceos consumidos en el Perú. [Estimation of methionine, cystine and cysteine in some crustaceans eaten in Peru.] An. Fac. Farm. Bioquím., Lima, 1952, 3, 141-149. [Lab. Control, Inst. Sanitas, Lima.]*

Methionine, cystine and cysteine were estimated in 4 species of Crustacea from the Peruvian coast, *Bithynis caementarius*, *Cancer polyodon*, *Panulirus ornatus*, and *Penaeus stylirostris*. For 5 samples of each species in the order given, the averages in g. per 100 g. pure protein were: methionine 2.41, 3.17, 2.40, 2.20; cystine 1.63, 1.93, 2.76, 1.66; cysteine 0.27, 0.68, 0.65, 0.52. The results are also given as percentages in the fresh and dried samples.—M. B. Richards.

2877

BLOSSER, T. H., ABBITT, W. H., SHAW, A. O., ASHWORTH, U. S. and SMITH, E. P. *The composition of foreign and domestic bone meals used in livestock feeding. J. Animal Sci., 1954, 13, 152-159. [Washington Agric. Exp. Stat., Pullman.]*

Twenty-two samples of bonemeal, 14 of foreign and 8 of domestic [U.S.] origin, were analysed. Four appeared to be contaminated, possibly with raw rock phosphate. Omitting these, the average composition was: protein 7.59, ether extract 0.93, ash 81.09, Ca 31.70, P 13.73, Mg 0.64 and S 0.22 per cent. Average contents of other elements estimated spectrographically were: Al 2344, Ba 361, Cu 16, F 803, Fe 964, Mn 49, Na 5000, Sr 2433, and Zn 489 p.p.m. of rehydrated ash. In addition, B, Cr, Mo, Si, Ag, Ti and V were found in one or more samples.—P. C. Jowsey.

FOODSTUFFS OF VEGETABLE ORIGIN

General

2878

MAGGIOLO FIGARI, F. *Valoración del ácido glutámico en alimentos. [Estimation of glutamic acid in foods.] An. Fac. Farm. Bioquím.,*

Vol. 24, No. 3

Lima, 1952, 3, 125-131. [Lab. Bromatol., Univ. Lima.]

Estimations of glutamic acid were made on plant products by the method of Orthner and Reichel (Practicas Quím. Org., 1943). For substances analysed in the fresh state the values obtained, per cent., were: artichoke 0.835, olive 0.744, beetroot 0.667, celery 0.6655, egg-plant 0.625, carrot 0.603, and turnip 0.4275. Dried apricot and dried peach contained, respectively, 1.883 and 1.127 per cent.—M. B. Richards.

2879

JANES, B. E. *Composition of Florida-grown vegetables. 3. Effects of location, season, fertilizer level and soil moisture on the mineral composition of cabbage, beans, collards, broccoli and carrots. Florida Agric. Exp. Stat. Bull. No. 488, December 1951, pp. 32.*

Two varieties of cabbage, 2 of beans [species not stated], 1 of broccoli, 1 of collards and 2 of carrots were grown at several stations and received fertiliser at 3 levels as previously described (Abst. 4819, Vol. 20). Total and dry matter yields, Ca, Mg, K, Na, Mn, Fe, S and P were estimated in all samples and the data are given in detail. Soil samples were analysed also.

The largest differences in mineral composition were associated with type of crop and location. Fertiliser level had only a slight effect.

To investigate further the effect of soil conditions, 2 varieties of beans and 1 of cabbage were grown on plots receiving irrigation water in 3 treatments; light, heavy and heavy in 2 equal applications. The control plot was not irrigated. Irrigation affected the mineral composition of the fresh vegetables; those heavily irrigated had reduced amounts of minerals, but on a dry matter basis there was, with minor exceptions, little difference.

In general, Ca, Mn and Fe contents were related to the physical and chemical characteristics of the soil; Na was influenced by the amount added to the soil, and Mn and Fe were affected by soil acidity. P in the vegetables was not correlated with the acid-soluble P in soil.—P. C. Jowsey.

Cereals

2880

CHAMBERS, W. E. *Nutrient composition of the produce of the Broadbalk continuous wheat experiment. 1. Changes over seventy years. 2. Changes occurring during one season's growth. J. Agric. Sci., 1953, 43, 473-478; 479-484. [Rothamsted Exp. Stat., Harpenden, Herts.]*

1. The changes in yield, K, Ca, Mg and Na over a 70-year period are described in detail and data for grain and straw showing the mean values and

the mean changes per decade are presented for 9 fertiliser treatments.

A method of estimating minerals by the Lunde-gårdh flame method of spectrography is described; it compares favourably in accuracy with gravimetric analysis.

2. K, Ca, Mg and Na were estimated spectrographically in ears, stems and roots of wheat from 8 Broadbalk plots which had received different fertiliser treatments. Samples were taken at 3-weekly intervals from May to early August 1945.

On all plots the concentrations of nutrients in all parts of the plants decreased during growth. Fertiliser treatment affected the composition of all parts except the ears. The data are given in detail.—P. C. Jowsey.

Legumes

2881

CURINI GALLETI, A. Bersim. Trifoglio alessandrino, o egiziano (*Trifolium Alexandrinum* L.). [Berseem. Alexandrine or Egyptian clover (*Trifolium alexandrinum*, L.).] *Riv. Zootec.*, 1954, 27, 14.

A description of the plant, its feeding value and composition. It is resistant to drought, responds readily to fertilisers, and is slightly richer in nutrients than red clover.—T. D. Bell.

2882

HOLMES, P. The amino-acid composition of certain seed proteins. *Austral. J. Exp. Biol. Med. Sci.*, 1953, 31, 595–602. [Inst. Agric., Univ. W. Australia.]

In extension of earlier work (Abst. 3262, Vol. 21) 15 amino-acids were estimated in the acid hydrolysates (alkaline for tryptophan) of the "whole" proteins from legume seeds and other materials previously analysed for arginine. The amino-acids were separated by paper chromatography, the methods used being based on the work of Consden *et al.* (*Biochem. J.*, 1944, 38, 224). A preliminary investigation showed considerable losses of amino-acids during hydrolysis, amounting, for individual acids, to from 4.6 to 37.6 per cent. The final results were corrected for these losses. Compared with whole egg protein as standard, the amino-acids limiting the nutritive value of the seed proteins were methionine in lupin seeds; methionine and isoleucine in vetch seeds; methionine, isoleucine and valine in peas; isoleucine, threonine and methionine in subterranean clover seed; and isoleucine and methionine in linseed. There appears to be a general deficiency of isoleucine in legume seeds.—W. Godden.

2883

HOPKINS, C. Y. and CHISHOLM, M. J. Some fatty acids of peanut, hickory, and acorn oils.

Canad. J. Chem., 1953, 31, 1173–1180. [Div. Pure Chem., Nat. Res. Council, Ottawa.]

Groundnut (*Arachis hypogaea*, L., var. Spanish) oil contained the following fatty acids expressed as percentages of the total fatty acids: arachidic 1.5, behenic 3.4, 11-eicosenoic 1.6, docosenoic 0.2. Hexadecenoic acid was not detected. Hickory (*Carya cordiformis*, Koch) nut oil contained the following acids: palmitic 6, stearic 1, higher saturated acids 0.5, oleic 72, linoleic 19. Higher monoenoic acids could not be identified. Acorn (*Quercus alba*, L.) oil contained the following acids: palmitic 10, stearic 2, oleic 48, linoleic and other polyenoic 40; eicosenoic acid was not detected.

RICE, A. C. and PEDERSON, C. S. **Chromatographic analysis of organic acids in canned tomato juice, including the identification of pyrrolidonecarboxylic acid.** *Food Res.*, 1954, **19**, 106-114. [New York State Agric. Exp. Stat., Cornell Univ., Geneva.]

The organic acids in 9 samples of 2-year-old canned tomato juice were estimated chromatographically. The average total acidity was 0.521 per cent.; of this 64.7 per cent. was citric acid, 4.5 per cent. malic acid and 30.1 per cent. pyrrolidonecarboxylic acid, with traces of acetic and lactic acids in some samples. Pyrrolidonecarboxylic acid was not present in freshly prepared tomato juice. Its presence was due to changes during processing and storage.—W. Godden.

FRÖLICH, A. **Experiments with different treatments of rape seed meal. 1. Review of literature and preliminary findings.** *Kgl. Lantbrukshögsk. Ann.*, 1953, **20**, 105-116. [Nat. Animal Exp. Stat.]

The literature is briefly reviewed. Several methods of removing the toxic principle(s) from rapeseed meal were used, including extraction with water or ethanol; fermenting with or without subsequent ether extraction; heating to 100° or 150° C. for 24 and 5 hr., respectively. The different samples were given to groups of 5-week-old Single Comb White Leghorn cockerels for 3 weeks at a level of 10 per cent. of the basic feed. At the end of the test 4 birds from each group were killed and their thyroids were examined.

The results indicated that rapeseed meal does not contain glucoside-splitting enzymes. Cold water and 70 per cent. aqueous ethanol were equally effective in removing mustard oil and some of the thioxazolidone. Dry heating above 130° C. destroyed either the toxic principles themselves or the ability of the glucosides to split into toxic substances.—P. C. Jowsey.

Vol. 24, No. 3

2892

FERNANDEZ F., Y. **Estudio químico bromatológico del aceite de "Sapindus saponaria" (boliche). [Chemical and bromatological study of the oil of Sapindus saponaria.]** *An. Fac. Farm. Bioquím., Lima*, 1952, **3**, 122-124. [Lab. Bromatol., Univ. Lima.]

Oil was extracted from the ground seeds of *Sapindus saponaria* by a solvent process; a yield of 35 per cent. was obtained. The oil was viscous and golden yellow and had an agreeable taste.

Data are presented for its chemical and physical characteristics. Total fatty acids varied between 85 and 90 per cent.; solid and liquid fatty acids amounted to 23 to 24 and 70 to 74 per cent., respectively. Stearic, oleic and palmitic acids amounted to 4 to 6, 40 to 46 and 12 to 14 per cent., respectively.

The tree occurs in large numbers in Peru, and it may prove economical to collect the seeds for industrial extraction and subsequent processing for a variety of purposes.—P. C. Jowsey.

2893

MONTGOMERY, E. M. and WEAKLEY, F. B. **Carbohydrate composition of hydrol.** *J. Assoc. Off. Agric. Chem.*, 1953, **36**, 1096-1108. [Res. Lab., U.S. Dept. Agric., Peoria 5, Ill.]

Hydrol is a carbohydrate-rich, molasses-like syrup obtained as a by-product in the manufacture of industrial maize sugars. It is used in making silage and in stock feeds. Analyses of 2 samples showed them to contain, per cent., water 26.0, 25.5; protein 0.2, 0.2; ash 8.8, 9.6; dextrose 40.8, 40.9; disaccharides 19.0, 19.0; higher oligosaccharides 5.3, 4.9.—W. Godden.

SYNGE, R. L. M. and WOOD, J. C. **Diffusible peptide-like and glycosidic constituents of Italian rye grass.** *Biochem. J.*, 1954, **56**, xix. [Rowett Res. Inst., Bucksburn, Aberdeen-shire.]

2895

NATH, N. and DAS, N. B. **Effect of monthly cuts on the chemical composition of some indigenous grasses of India.** *Indian J. Vet. Sci.*, 1953, **23**, 185-204. [Indian Agric. Res. Inst., New Delhi.]

Detailed results are presented for the composition of 10 species of indigenous grasses sampled monthly for 6 months (7 cuts) from May 1949.

P. C. Jowsey.

2896

DOUGALL, B. M. **The composition of *Agrostis setacea*, the bristle-leaved or heath bent grass.**

J. Sci. Food Agric., 1954, **5**, 132-134. [Seale-Hayne Agric. Coll., Newton Abbot, Devon.]

Data are presented for the composition of *Agrostis setacea* sampled 6 times between March and November 1950.

The results indicated that the species is late-maturing and reaches its maximum crude protein content, 11.38 per cent. of the dry matter, in July. The highest digestibility coefficient for crude protein was 69.80 and was obtained in June. The ash was low in Ca and P; the maximum values for CaO and P₂O₅ were 0.175 and 0.291 per cent. of the dry matter, respectively, and were found in July.

It was concluded that *A. setacea* is a poor source of digestible protein and minerals and is of value for only a comparatively short season, chiefly to sheep, since cattle found it unpalatable.

P. C. Jowsey.

2897

DOUGALL, B. M. **The composition and probable feeding value of *Triodia decumbens*.** *J. Sci. Food Agric.*, 1954, **5**, 134-136. [Seale-Hayne Agric. Coll., Newton Abbot, Devon.]

Samples of *Triodia decumbens* were collected on 6 occasions from March to November 1950. Data on composition are presented in detail. Crude protein reached a maximum of 10.88 per cent. of the dry matter in May and the digestibility of this constituent reached its highest value, 72.51 per cent., in the same month. Ca and P were comparatively low at all times.

It was concluded that although the grass is inferior to several other hill species it is of some value to sheep, if only because it is available at a time of general scarcity.—P. C. Jowsey.

2898

DOUGALL, H. W. **Kikuyu grass. 1. Seasonal variation in composition of degenerate and productive pastures.** *East African Agric. J.*, 1953, **19**, 74-80. [Dept. Agric., Kenya.]

Crude protein, crude fibre, carbohydrate, carotene, P₂O₅ and CaO were estimated in samples of Kikuyu grass (*Pennisetum clandestinum*) collected at intervals over 12 months from a young pasture and for 6 months from a 7-year-old pasture. The results are given in detail and data for naturally growing, "wild", Kikuyu grass are given for comparison.

Crude protein was consistently higher and crude fibre generally lower in the young than in the old grass. In June only was the protein content of young pasture herbage lower than that of the wild grass.

Old, unproductive Kikuyu pastures generally have a thick mat of roots and undecomposed plant debris over the soil surface and the first step in regenerating such areas is to rip away and break

up this mat. Work is continuing to estimate the effect of fertilisers on regenerated old Kikuyu pasture.—P. C. Jowsey.

2899

WALKER, T. W., ADAMS, A. F. R. and ORCHISTON, H. D. **The use of fertilizers on herbage cut for conservation. 4. The effect of rates, methods of application and forms of fertilizer nitrogen on the yields of dry matter and nitrogen of grasses and clovers in a ryegrass and white clover sward, cut at different stages of growth.** *J. Brit. Grassland Soc.*, 1953, **8**, 281-299. [Canterbury Agric. Coll., New Zealand.]

For previous parts see Absts. 1470, 2816, 4083, Vol. 23.

A 3 × 3 × 3 factorial trial of single replication was laid down on a ryegrass-white clover sward to test 3 sources of N, urea (40 per cent. N), nitrolime (20.5 per cent. N) and sulphate of ammonia (20.7 per cent. N), applied at 2 rates, 0.3 and 0.6 cwt. N per acre, with a control, untreated plot, with 3 types of cutting, for dried grass (4 cwt.), for silage (3 cwt.) and for hay (2 cwt.). A secondary trial contrasted 2.4 cwt. N per acre as urea applied in 1 massive or in 4 equal dressings. This herbage was cut 5 times for dried grass. Yields of fresh and dry matter and N were estimated for each cut. The trial lasted about 170 days.

The results are presented and analysed in detail. Ammonia depressed the yield of clover more than the other forms of N used and although it appeared to increase the yields of dry matter and N in the grasses more than the other fertilisers, the differences were not significant.

It is suggested that urea would probably be the best and cheapest form of N to import into New Zealand for special purposes such as out-of-season production of grazing on ryegrass.

It was concluded that there is little to be gained in yield of either dry matter or crude protein from the use of moderate amounts of N fertiliser on swards containing a high proportion of clovers cut for conservation in any form.—P. C. Jowsey.

2900

ØDELIEN, M. **The effect of fertilizer rates on the sugar content of timothy.** *Acta Agric. scand.*, 1954, **4**, 67-70. [Inst. Fertilization and Soil Management, Agric. Coll. Norway.]

Sucrose and reducing sugars expressed as glucose were estimated in samples of timothy collected immediately before each of 2 hay cuts during the years 1949 to 1952 inclusive from fields that had received different amounts of Fullgjödsel A (N 13.5, P 6.0, K 16.0 per cent.), K fertiliser (K 33 per cent.) and, after the first cut, nitrate of lime.

The sucrose contents fell in all first-cut samples as the amount of fertiliser increased. From no dressing to the heaviest (900 kg. Fullgjödsel A plus 225 kg. K fertiliser per hectare) the relative amounts of sucrose present were 100, 67, 48, 45 per cent. No definite trend for the second cut was noted. No clear connection between fertiliser level and glucose content was established for either cut.—P. C. Jowsey.

2901

HILDER, E. J. **Some aspects of sulphur as a nutrient for pastures in New England soils.** *Austral. J. Agric. Res.*, 1954, **5**, 39–54. [Div. Plant Indust., C.S.I.R.O., Reg. Pastoral Lab., Armidale, N.S.W.]

The beneficial effects of S fertilisers on the yield of subterranean clover growing on S-deficient soils in the New England region of New South Wales were studied. Detailed results are given.

P. C. Jowsey.

2902

SEARS, P. D., LAMBERT, J. P. and THURSTON, W. G. **Pasture growth and soil fertility. 6. Influence of red and white clovers, superphosphate, lime, and sheep grazing, on pasture yields and composition, and on the growth of subsequent forage crops; results at Gore and Lincoln.**

SEARS, P. D. **7. General discussion of the experimental results, and of their application to farming practice in New Zealand.** *N.Z. J. Sci. Technol.* [A], 1953, **35**, 199–220; 221–236. [Grasslands Div., D.S.I.R., Palmerston North, N.Z.]

6. The trials made at Gore and Lincoln were similar to previous trials at Palmerston North (Abst. 1680, Vol. 24).

The results showed that the same general improvement resulted from the presence of clovers and the return of dung and urine, but differences due to climate and level of soil nutrients occurred.

At both Gore and Lincoln, response to superphosphate and lime was greater than at Palmerston North. Pedigree New Zealand white clover was more effective in increasing soil N than Pedigree red clover, but the results were not conclusive, since no trial to test the effectiveness of the associated *Rhizobia* were made, nor any to test the effectiveness of nutrients other than lime and P. Yields of forage crops grown after the pasture trials were correlated with the preceding pasture yields as previously found.

The evidence emphasised the need for increasing the soil nutrients, especially N, in order to attain the yields that are possible under New Zealand climatic conditions.

7. The data presented in the 6 preceding reports are discussed in relation to the basic concept of

Vol. 24, No. 3

pasture growth and soil fertility increase in New Zealand and to some particular aspects of farming practice.—P. C. Jowsey.

2903

ANDREWS, E. D. **Effectiveness of cobalt sulphate applied to cobalt-deficient pumice land from the air.** *N.Z. J. Sci. Technol.* [A], 1953, **35**, 301–310. [Animal Res. Stat., Dept. Agric., Wallaceville.]

A pasture of varied topography, the herbage of which contained on the average 0.05 p.p.m. Co on a dry matter basis was top-dressed from the air with a solution of cobalt sulphate at the rate of 20 oz. of the hydrated salt per acre.

The average Co content of the herbage was raised to 0.98 p.p.m. immediately after top-dressing. A year later it was 0.13 and a further year later 0.10 p.p.m. on a dry basis.

P. C. Jowsey.

2904

RØYSET, S. **Eit 5-årigt forsøk med kopar og molybden til eng. [A 5-year experiment in applying copper and molybdenum to pasture.]** *Forskning og Forsøk Landbruket*, 1953, **4**, 401–422. [Statens Forsøksgård Fureneset, Norway.] English summary.

A manurial trial continued for 5 years on this west coast experiment station is described in detail. All the plots had N, P, K, Mg, Mn and B and the experimental plots received copper sulphate, ammonium molybdate or both. In 1950, after the first cut, and in 1952, all the plots were sprayed with cobalt chloride. Analyses are reported. The increases in yield with Mo indicated a deficiency of that element. Mo alone reduced, and Cu alone raised Cu, Mg, protein and fat in the crop. These elements singly and together reduced Co by about the same amount.—I. Leitch.

2905

DAVIES, E. B. and GRIGG, J. L. **Molybdenum and its use in grassland production.** *N.Z. J. Agric.*, 1953, **87**, 561–567. [Soil Res. Stat., Rukuhia.]

2907

KOLOUŠEK, J. and COULSON, C. B. **Plant proteins. 1. Extraction of hay proteins and nitrogen distribution.** *J. Sci. Food Agric.*, 1954, **5**, 126–132. [Agrobiochem. Lab., Fac. Agric., Technická 1903, Prague XIX, Czechoslovakia.]

Samples of red clover, orchard grass and timothy cut at the mature stage, and of alfalfa cut at 5 stages of growth, were examined. Protein preparations were obtained from air-dried samples by extracting with 0.2 per cent. NaOH and precipitating with glacial acetic acid. N was estimated in the material insoluble in NaOH and in the material soluble in NaOH but not precipitated by acetic acid. The protein preparation was freed from chlorophyll and lipids by extraction with ether. True protein and pepsin-insoluble N were estimated in the original samples. In the alfalfa samples the protein N obtained by alkali extraction was linearly related to the true protein N and the alkali-insoluble N was of the same order as the pepsin-insoluble N.—W. Godden.

2908

SMITH, A. M. **Seasonal variation in the quality of grass silage.** *J. Sci. Food Agric.*, 1954, **5**, 48–51. [Edinburgh and E. Scotland Coll. Agric., 13 George Sq., Edinburgh 8.]

Dry matter, crude protein and pH were estimated in 1244 samples of grass silage examined for advisory purposes over the 4 seasons 1949 to 1953.

The following results were obtained: 41 per cent. of the samples contained between 11 and 14 per cent. crude protein; 58 per cent. contained more than 20 per cent. dry matter; 63 per cent. were well preserved. In a dry year the proportion of samples poor in protein increased and in a wet year the reverse was true. The dry matter content varied in the opposite direction.

It was concluded that good conservation, resulting from satisfactory fermentation and reduction of pH to below 4.5, is most readily obtained when the crop contains more than 20 per cent. dry matter. Very wet material should be allowed to dry off a little before ensiling.

P. C. Jowsey.

2909

BARNETT, A. J. G. and DUNCAN, R. E. B. **Volatile fatty acids in laboratory and field silage.** *J. Sci. Food Agric.*, 1954, **5**, 120–126. [Div. Agric. Biochem., Dept. Biol. Chem., Univ. Aberdeen.]

Volatile fatty acids were estimated in samples of minced grass or kale which had been incubated at temperatures from 17° to 62° C., under aerobic or anaerobic conditions, for periods up to 20 weeks. Formic acid and acids higher than C₆ were not found. The principal acid present in all samples and at all periods was acetic; the next in amount was butyric acid. In samples of field silage, straight-chain acids from C₁ to C₈ were present; the only branched-chain acid present was isovaleric acid. The principal volatile acid was acetic acid.

W. Godden.

2910

DIJKSTRA, N. D. Verliezen bij het inkuilen van bietenkoppen en -blad. [Losses in ensiling beet tops and leaves.] *Landbouwwoorlichting*, 1953, **10**, 358–366. [Rijkslandbouwraproefstat., Hoorn.]

Silage was made in several ways: from chopped material in a drained and an undrained silo, from unchopped material in a drained silo, chopped in a wooden container on the ground, unchopped in a stack on the ground, completed in one day or over 5 days. The unchopped material heated, the chopped did not; the unchopped contained about 0.2 per cent. butyric acid, the chopped none. Sugar disappeared from all samples. In comparison with the original analysis, protein, fibre and ash, including Ca and Cu, rose; Mg and P were unaltered and K, Na, Cl and S were reduced. Loss of organic matter was from 25 to 32 per cent. and of crude protein from 15 to 25 per cent. except for the last, 5-day, stack silage, where it was 53 per cent. Unchopped beet lost more protein than chopped. Otherwise there was little difference attributable to the way of making the silage.—I. Leitch.

NOVOKHATSKII, I. P. and KALININ, S. K. [Fluorine content of some natural Kazakhstan waters according to spectrum analysis.] *Dokl. Akad. Nauk. S.S.S.R.*, 1953, **93**, 289.

2912

WILSON, D. C. **Fluorine content of some Nigerian waters.** *Nature*, 1954, **173**, 305. [Lab. Human Nutrit., Univ. Oxford.]

The rocks of the Central Plateau are known to have a high F content, but of 10 samples of water analysed in this area none had more than 0.4 p.p.m. A mild degree of dental fluorosis was seen among tribesmen living on the Plateau. F occurs also among minerals in the Niger and Benue valleys, but of 65 schoolgirls between 7 and 15 years of age examined, only 8 showed mottling of the teeth. In another area where well waters had F contents from 0.1 to 1.2 p.p.m., 6 of 38 girls examined had a moderate amount of mottling.

It was concluded that the F in these pre-Cambrian rocks dissolves in drinking waters to a small extent only.—D. Harvey.

2913

WOJCIECHOWSKA, W. and KOŁACZKOWSKI, S. Fluor w wodach na terenie województwa poznańskiego. [Fluorine in water in the province of Pozan.] *Rocz. Państwowego Zakł. Hig.*, 1953, No. 3, 239–246. [Stac. Sanit.-Epidemiol., Poznan.] Russian and French summaries.

N.A. and R., July 1954

The mean F content of the water supply and of well water in Poznan was 0.23 mg. per litre with a variation from 0 to 1.1 mg., the highest value being found in the district of Kalisz and attributed to the presence of calcareous Jurassic rocks. It is suggested that F should be added to the water supply in order to prevent dental caries. (From summary.)—J. S. Thomson.

2914

VENKATESWARLU, P. and NARAYAN RAO, D.
Studies in endemic fluorosis: Visakhapatnam

and suburban areas: distribution of fluorine in local waters. *Indian Med. Gaz.*, 1953, **88**, 262–265. [Dept. Biochem., Andhra Med. Coll., Visakhapatnam.]

F was estimated in over 170 samples of surface, spring and well waters from the Visakhapatnam district. The content ranged from a trace to 11 p.p.m. but was generally between 0.5 and 2 p.p.m. Some places showed wide local variations, ascribed to the presence of F-bearing apatite rocks. The occurrence of endemic fluorosis is considered likely.—W. M. Deans.

POLISTER, B. H. and MEAD, J. F. **Irradiation effects. Effect of certain vitamins and anti-oxidants on irradiation-induced autoxidation of methyl linoleate.** *J. Agric. Food Chem.*, 1954, **2**, 199–202. [Sch. Med., Univ. California, Los Angeles.]

Emulsions of methyl linoleate with a uniform particle size of 5 μ . were exposed to X-rays at 25 r per min.

The presence of catalase or hydrogen peroxide did not affect the formation of hydroperoxides as a result of exposure to X-rays. Vitamin A alone was not affected by X-rays; when added to the linoleate it was completely destroyed at low concentrations but at high concentrations it inhibited the oxidation process. Tocopherol and Ionol, a commercial anti-oxidant, were effective against oxidation at concentrations so low that the extent of their own destruction was not measured. Calciferol was not affected by X-rays when added to the emulsions but was only partly effective in protecting the linoleate. Ascorbic acid, at a concentration of 9.4 mol. per cent. or more, completely protected the linoleate, and at 5.0 mol. per cent. was still partly effective.

Glutathione enhanced the oxidation of linoleate and was itself extensively oxidised even before exposure to X-rays. When cysteine was added the gradual appearance of an absorption peak was consistently observed and it is thought that formation of a compound with methyl linoleate took place, which was catalysed by peroxide.

Vol. 24, No. 3

It is concluded that if fatty foods are sterilised by means of X-rays, anti-oxidants can be used to prevent destruction of vitamins.—V. R. Jackson.

SQUIBB, R. L., GUZMÁN, M. and SCRIMSHAW, N. S. Dehydrated desmodium, kikuyu grass, ramie, and banana leaf forages as supplements of protein, riboflavin, and carotenoids in chick rations. *Poultry Sci.*, 1953, **32**, 1078-1083. [Inst. Agropecuario Nac., Guatemala.]

For a series of growth trials with chicks forage meals were prepared from desmodium (16 in. high, stems and leaves), kikuyu grass (5 in. high), ramie (16 in. high, entire plant) and banana leaves with the heavy centre vein removed, dried at 115° F. in moving air. The meals contained, per cent., respectively, crude protein 12.9, 16.3, 22.4 and 16.1, crude fibre 20.7, 19.0, 11.9 and 18.6, and ash 7.4, 9.7, 17.7 and 12.1. Analysis showed that the experimental meals were equal or superior to average alfalfa meals in their content of carotenoids, vitamin B₁, riboflavin and nicotinic acid. The banana leaf meal had the high value of 45.6 p.p.m. riboflavin.

In the first trial 6 groups of chicks, receiving a low-lysine ration of sesame oilmeal 45, yellow maize meal 50, and vitamin and mineral supplements, finished at 5 weeks of age with a mean weight of 186 g. Comparable groups receiving the same ration supplemented with 20 per cent. of kikuyu grass, ramie or banana leaf meal, at the expense of sesame and maize, weighed 238, 249 and 237 g., respectively.

In two further trials, each meal included as 5 per cent. of the ration proved a satisfactory source of riboflavin and carotene. It is concluded that with care in selection of forage and in drying, tropical forage meals can be prepared equal in nutritive value to the alfalfa meals used for poultry feeding in temperature climates.—K. J. Carpenter.

WU, C. H. and FENTON, F. Effect of sprouting and cooking of soybeans on palatability, lysine, tryptophane, thiamine, and ascorbic acid. *Food Res.*, 1953, **18**, 640-645. [State Coll. Home Econ., Cornell Univ., Ithaca, N.Y.]

Soya beans of the Seneca variety were sterilised with hypochlorite and then allowed to germinate in the dark for from 6 to 7 days at from 17° to 27° C. Rootlets were removed, leaving an edible portion of from 62 to 87 per cent. The sprouted beans were cooked by boiling in unsalted or salted water or in a little salted water with lard. Estimations were made, in unsprouted, sprouted and cooked beans, of lysine and tryptophan microbiologically, vitamin B₁ by the thiochrome method, and ascorbic acid by the xylene method. Assessments were made of palatability.

Lysine content in unsprouted beans was 1767 mg. per 100 g., of which only 36 per cent. was found in the edible portion of the sprouted beans. The percentage retention after cooking by the 3 methods was 92, 93 and 89, respectively. Unsprouted beans contained 456 mg. tryptophan per 100 g., of which 61 per cent. was retained in the edible portion after sprouting. Retention after cooking ranged from 77 to 85 per cent.

Unsprouted beans contained 1.1 mg. vitamin B₁ per 100 g., of which 48 per cent. was retained in the edible portion after sprouting. Retention after cooking ranged from 63 to 72 per cent. Of ascorbic acid in mg. per 100 g., unsprouted beans contained 4.2, uncooked sprouts 10.6 and beans 20.6, but on a dry weight basis sprouts contained twice as much as beans, 182.8 and 76.0, respectively. Retention after cooking and holding for 1 hr. ranged from 27 to 38 per cent.

Percentage moisture contents were for unsprouted beans 12, sprouts 94, beans 73 and sprouted beans 83.

Differences in palatability after cooking by the 3 methods were not important.—V. R. Jackson.

TEPLY, L. J., DERSE, P. H., KRIEGER, C. H. and ELVEHJEM, C. A. Nutritive value of canned foods. Vitamin B₆, folic acid, beta-carotene, ascorbic acid, thiamine, riboflavin, and niacin content and proximate composition. *J. Agric. Food Chem.*, 1953, **1**, 1204-1207. [Wisconsin Alumni Res. Found., Madison.]

The various nutrients were estimated in 48 canned products of animal and vegetable origin, as part of the nutrition programme of the National Canners Association and Can Manufacturers Institute. Of 48 products, 16 were analysed for the

N.A. and R., July 1954

first time, and, of the remainder, additional samples were examined in order to complete the programme with respect to geographical distribution and volume of production.

Values for β -carotene, ascorbic acid, vitamin B₁, riboflavin and nicotinic acid and for proximate composition confirmed those previously reported (*Nutrition Rev.*, 1949, 7, 142; 144). On the basis

of total edible content, the values for vitamin B₆ were highest in pineapple juice, maize, tomatoes, cherries and meat products, and for folic acid in spinach, asparagus, beans, peas, blackberries, boned chicken and oysters.

The results include new information considered of use to dietitians.—V. R. Jackson.

BERGER, S. Metoda ilościowego oznaczania β -karotenu (prowitamin A) i sumy karotenoidów w niektórych produktach roślinnych. [A method for estimating β -carotene (provitamin A) and total carotenoids in some plant materials.] *Rocz. Państwowego Zakł. Hig.*, 1953, No. 4, 473–479. Russian and English summaries.

Four methods of estimating β -carotene and total carotenoids in fresh and dried plant material (Abst. 1954, Vol. 11; 1003, Vol. 13) were compared. Some modifications are suggested and the results of 81 estimations are tabulated. (From summary.)—W. Godden.

2928

BLAIN, J. A., HAWTHORN, J. and TODD, J. P. The bleaching of carotene by a lipoxidase-linoleate system. *J. Sci. Food Agric.*, 1953, 4, 580–587. [Food Sci. Sect., Royal Tech. Coll., Glasgow.]

A system for studying the coupled oxidation of carotene by lipoxidase is described. Buffer solution, aqueous sodium linoleate, a solution of carotene in acetone and ethanol, and lipoxidase from soya beans were mixed and shaken for 1 min. Sodium hydroxide was then added to stop the reaction and to clarify the solution, and the carotene remaining was estimated absorptiometrically.

The effect of pH was studied in detail and is discussed. The pH-activity curve was complex with a maximum at pH 5. The kinetics of the system are described and several curves are presented. Certain characteristics of the linoleate system in absence of carotene also were studied by measuring diene conjugation spectrophotometrically at 234 m μ . The light absorption curve of carotene in the system was different from that in chloroform solution; evidently its state of dispersion was different in aqueous solution and in organic solvents.

It is considered that the system may be used to measure the lipoxidase activity of soya beans, wheat products and possibly other materials, the method being, for instance, suitable for industrial control work.—V. H. Booth.

DEUEL, H. J. (Jr.), GANGULY, J., WALLCAVE, L. and ZECHMEISTER, L. Provitamin A activity of a structural isomer of cryptoxanthin and its methyl ether. *Arch. Biochem. Biophys.*, 1953, 47, 237–240. [Dept. Biochem., Univ. S. California, Los Angeles.]

The activity as provitamin A of isocryptoxanthine or 4-hydroxy- β -carotene and its methyl ether was compared with that of all-*trans*- β -carotene biologically with rats. The carotene was given in daily amounts of 0.5 and 1.0 μ g., and the two test substances in daily amounts of 1, 2 and 4 μ g. When the gain in weight was plotted against the logarithm of the dose, isocryptoxanthine and its methyl ether had about half the vitamin A potency of all-*trans*- β -carotene.—R. J. Ward.

2930

GANGULY, J., KRINSKY, N. I., PINCKARD, J. H. and DEUEL, H. J. (Jr.) Untersuchungen über den Carotinoid-Stoffwechsel. 14. Biologische Wirksamkeit von Echinenon. [Studies of carotenoid metabolism. 14. Biological activity of echinenone.] *Hoppe-Seyler's Ztschr.*, 1953, 295, 61–66. [Dept. Biochem. Nutrit., Univ. S. California, Los Angeles.]

Echinenone, isolated from the Californian sea urchins, *Strongylocentrotus purpurata* and *S. franciscanus*, had 54 per cent. of the activity of all-*trans*- β -carotene in growth tests with rats. When large doses of echinenone were given to deficient animals the absorption spectrum of the liver oil gave evidence that vitamin A was formed, which was confirmed by mixed fluorescence chromatography of liver extracts from rats given echinenone or β -carotene.—T. Moore.

COLLINS, F. D., GREEN, J. N. and MORTON, R. A. Studies in rhodopsin. 7. Regeneration of rhodopsin by comminuted ox retina. *Biochem. J.*, 1954, 56, 493–498. [Dept. Biochem. Univ. Liverpool.]

Satisfactory regeneration of rhodopsin has already been achieved with frog and rat retinas (Abst. 2832, Vol. 23) but their small size was a

drawback. The method of preparing comminuted ox retina is described in detail, but regeneration of rhodopsin from synthetic vitamin A by the retina preparation was not at first attained. It was, however, established that the preparation was capable of synthetic phosphorylation processes. Tween 80 was adopted for dispersal of vitamin A in preference to Dispersol A. In contrast with rat eye tissue, better regeneration was obtained with retina only than with retina and choroid. For the incubation medium, vitamin A and phosphate buffer only were necessary; adenosinetriphosphate need not be included. Delay of as little as 30 min. adversely affected the power of regeneration; the effect of delay was counteracted by addition of diphosphopyridine nucleotide. Presence of pyridoxal phosphate increased the amount regenerated. Exposure to light of retinene or synthetic vitamin A before incubation gave a greater amount of regeneration. The power of regeneration was in the insoluble part of the retina preparation, showing that no water-soluble enzymes took part. The mechanism of regeneration is discussed.—E. M. Hume.

2932

BIERI, J. G. and POLLARD, C. J. **Studies of the site of conversion of β -carotene injected intravenously into rats.** *Brit. J. Nutrition*, 1954, **8**, 32-44. [Dept. Biochem. Nutrit., Univ. Texas Med. Branch, Galveston.]

Weanling rats depleted of vitamin A, but without signs of deficiency, were given a single oral or intravenous dose of 4.0 μ g. β -carotene in 1 per cent. Tween 40 or 18.8 μ g. carotene and 0.3 mg. α -tocopherol in 20 per cent. Tween 40. With the 4 μ g. dose the rats treated by injection grew better than those treated by mouth; with the dose of 18.8 μ g. carotene and 0.3 μ g. tocopherol those treated by mouth grew better than those treated by injection.

Rats which had shown signs of deficiency for 2 or 3 days were given a single dose of 5.2 μ g. carotene with or without tocopherol; the response to injection was very poor. With the oral dose the group given tocopherol put on more weight than those without it.

The average total carotene content of various tissues 4 hr. after a single injection of 69 μ g. carotene in aqueous dispersion is listed. On the average, 67.2 per cent. of the injected carotene was recovered. No carotene was found in the urine or faeces of rats 4 days after an intravenous injection of 96 μ g. solubilised carotene.

An intravenous injection of 100 μ g. carotene was given in aqueous dispersion; the carotene content of the serum after 5 min. was 2130 μ g. per 100 ml.; after 12 hr. it was 277, and after 48 hr. there was none. The concentration of vitamin A in the

serum reached a maximum of 134 μ g. per 100 ml., after 6 hr. The maximum concentrations of both carotene and vitamin A in the liver occurred after 12 hr., and in the kidneys after 18 hr.

Deficient rats were given either 76 μ g. carotene by intravenous injection or 152 μ g. by mouth. The vitamin A value for the serum of those treated orally and by injection was, respectively, 71 and 36 after 1 day, and 13.5 and 6.1 after 15 days.

When from 98 to 110 μ g. carotene were given in divided doses on 4 successive days either by mouth or by vein, the concentrations of vitamin A in the liver and kidneys were almost identical, but the serum of the injected animals had a slightly higher concentration of vitamin A and the liver a much higher concentration of carotene.

Rats subjected to anaesthesia, abdominal incision and handling of the viscera had an amount of vitamin A in the serum and liver 4 to 6 hr. after an intravenous injection similar to that in intact animals. Ligation of the bile duct or removal of the kidneys or of 60 to 70 per cent. of the liver did not impair the formation of vitamin A from carotene. When the entire small intestine was removed, the formation of vitamin A from injected carotene was similar to that in animals not so treated.—R. J. Ward.

HJARDE, W., NIELSEN, J. and POROTNIKOFF, O. **Utilization of carotene by dairy cows.** *Acta Agric. scand.*, 1954, **4**, 3-16. [Statens Vitaminlab., Copenhagen.]

Twenty-four Shorthorn or Black-spotted Danish Dairy cows aged from 2 to 12 years were divided into groups A, B, C and D, of 6 animals each. In a preliminary feeding period of 35 days all the cows received mixed fodder which supplied about 350 mg. carotene daily. There followed a transition period lasting 7 days and then 2 experimental periods of 30 and 40 days. During the transition and first experimental periods, group A received an intermediate amount of about 200 mg. carotene daily, given in the silage. Group B received a large amount of about 550 mg.; group C had 210 mg. carotene in solution in oil, and group D had a small amount of about 45 mg. from fodder, not silage. In the second experimental period the groups received approximately 350, 950, 890 and 45 mg. carotene, respectively, group C again being given its carotene in oil. Estimations at the end of the preliminary period and during the experimental periods of the amounts of carotene excreted in the faeces compared with the amounts supplied in the feed showed that the carotene was poorly utilised, and no better in group D which received barely enough to cover the normal vitamin A requirement. Analysis of the milk showed that after 20 days in the second experimental period the

N.A. and R., July 1954

vitamin A content in I.U. per g. butterfat was 23.3 in group A, 24.8 in group B and 24.7 in group C. The carotene content of the butterfat was higher in the last two groups. Values for both carotene and vitamin A were low in the milk from the cows in group D. Analysis of the liver of 8 animals killed at the end of the experiment showed no relation between the quantity of carotene given and the total amount of carotene and vitamin A found, but there was a consistent increase in the vitamin A content with increasing age.

I. M. Sharman.

CHANDA, R., CLAPHAM, H. M. and OWEN, E. C.

Dietary carotene and the degree of esterification of vitamin A in the milk and blood of cows.

Biochem. J., 1954, **56**, 453-458. [Hannah Dairy Res. Inst., Kirkhill, Ayr.]

Four lactating Ayrshire cows were maintained for 20.5 weeks on an experiment divided into 7 periods of about 3 weeks each. In periods 1, 3 and 6 the diet was free from carotene. In periods 2, 4 and 5 the diet included carotene as a natural constituent of dried grass and lucerne meals, and in period 7 the cows received fresh grass in a grazing trial. The carotene content of the feed in mg. per 100 g. was 2.96 in period 2, 5.26 in period 4, 6.28 in period 5 and 22.61 in period 7.

In confirmation of the authors' previous results, carotene deprivation caused the content of vitamin A alcohol in the milk to increase, the average values being 7, 6 and 6 I.U. per 100 ml. for the respective periods when carotene was present in the diet, and 13, 13.5 and 14 for the periods without carotene. The concentration of vitamin A alcohol in the blood was not affected by withdrawing carotene from the ration. In period 2 values for vitamin A ester in the blood ranged from 9.7 to 12.5 I.U. per 100 ml. but in period 3 fell to zero; the values rose to between 21.2 and 29.6 in periods 4 and 5 when carotene was present in the diet but fell again to zero in period 6 when the diet contained no carotene. From the present experiments and from earlier ones in which cows treated with thyroxine showed an increase in the content of vitamin A alcohol in the milk, it is concluded that increase of vitamin A alcohol is due to transfer of vitamin A to the milk from the liver.—I. M. Sharman.

2935

PATERSON, J. C. S. and WIGGINS, H. S. **An estimation of plasma vitamin A and the vitamin A absorption test.** *J. Clin. Pathol.*, 1954, **7**, 56-60. [Postgrad. Med. Sch., London.]

Vitamin A was estimated in specimens of heparinised plasma by extraction with *n*-heptane after addition of ethanol. The heptane extract was divided into 2 portions of which one was treated

for 3 hr. with ultraviolet light. The optical density of the non-irradiated portion was estimated at 327 m μ , the irradiated specimen giving the blank setting in a quartz spectrophotometer. A calibration curve was obtained by plotting the difference between the optical densities of irradiated and non-irradiated solutions of a sample of international standard vitamin A in heptane. Under the conditions used the destruction of vitamin A was shown to be complete within 3 hr.

Specimens of plasma from 2 patients with idiopathic steatorrhoea were examined before and 4, 8 and 12 hr. after the patients had been given, by mouth, 350,000 I.U. vitamin A ester in oil. The absorption curves were repeated with a similar dose of vitamin A emulsified with sorbitan monooleate. Values after 4 hr. were 43 and 102 I.U. vitamin A per 100 ml. when the vitamin was given in oil and 65 and 125 when given with the emulsifying agent. Eight patients with steatorrhoea and 11 normal subjects were given vitamin A at the rate of 7500 I.U. per kg. bodyweight, as crystalline vitamin A alcohol or palmitate dissolved in arachis oil. Flat absorption curves were obtained from patients with steatorrhoea; those of the normal subjects "peaked" after 4 hr., with plasma values between 600 and 1500 I.U. per 100 ml. It is suggested that though flat curves are not necessarily diagnostic of steatorrhoea, the finding of a plasma vitamin A value of 500 I.U. or more, 4 to 5 hr. after a dose of the vitamin of the order indicated, should almost certainly exclude a diagnosis of steatorrhoea.—I. M. Sharman.

BOBBY, F. C., THOMPSON, J. J. and BELWORTHY, W. R. **Feeding synthetic vitamin A to laying pullets.** *N.Z. J. Agric.*, 1953, **87**, 313-316. [Poultry Indust., Dept. Agric., Wellington.]

Pullets in 3 groups were given a basal diet with supplements of 2000 I.U. vitamin A and 200 I.U. vitamin D per 100 lb. mash. Groups 1 and 2, which were duplicates, were given vitamin D₃ and vitamin A as the synthetic palmitate and group 3 was given a fish liver oil. Records were made of egg production, food consumption, mortality and vitamin A content of the liver. In 44 weeks the average number of eggs was 150.6, 130.5 and 150.5, and the average feed consumption in lb. per head was 85.6, 85.7 and 91.0, respectively. There were 7 deaths in group 1, 5 in group 2, and 6 in group 3. The average vitamin A content of the liver in I.U. per g. was 912, 848 and 1072.—R. J. Ward.

2937

SKATIN, Y. D. **A-avitaminoz tzyplyat. [Vitamin A deficiency in chicks.]** *Veterinariya*, 1952, **29**, No. 8, 41-43. [Saratov. Mezhsovkh. Vet.-Bacteriol. Lab.]

The clinical and pathological features are described of an outbreak of disease in fowls, diagnosed as vitamin A deficiency. The condition responded well to administration of vitamin A concentrate and fish oil. Of eggs from the birds during the period of deficiency only 54.5 per cent. hatched, and the chicks showed signs of severe vitamin A deficiency from the first day. The response to treatment was unsatisfactory. It is suggested that, during incubation, changes occur in the gastro-intestinal tract which reduce the effectiveness of administered vitamins.—D. W. Taylor.

2938

HOEKSTRA, W. G., HALL, R. E. and PHILLIPS, P. H. **A study on the relationship of vitamin A to the development of hyperkeratosis (X disease) in calves.**

HOEKSTRA, W. G., DICKE, R. J. and PHILLIPS, P. H. **Production of hyperkeratosis in calves, with a topically applied oil-based insecticide carrier.** *Amer. J. Vet. Res.*, 1954, **15**, 41-46; 47-50. [Dept. Biochem., Univ. Wisconsin, Madison.]

Field studies showed that about 70 per cent. of calves suffering from some degree of hyperkeratosis (see next paragraph) had less than 10 μ g. vitamin A per 100 ml. blood plasma. A supplement of from 600,000 to 750,000 I.U. vitamin A for from 9 to 12 days usually resulted in a normal vitamin A value in the blood, less diarrhoea and coughing and improved appetite. In a controlled experiment 9 bull calves were divided into 3 groups, of which one received non-toxic pellets, and 2 received pellets known to have produced hyperkeratosis, of which one received in addition 25,000 I.U. vitamin A daily. During 5 weeks of milk feeding the vitamin A value in the plasma of the calves of the first group remained at about 14 μ g. per 100 ml. and that of the third group rose to about 20 μ g. per 100 ml. No sign of hyperkeratosis appeared. With the discontinuance of milk feeding, pellet consumption increased to 1 lb. per calf daily. The vitamin A value in the plasma of the group having toxic pellets without vitamin A showed a rapid decrease to about 2 μ g. per 100 ml.; the calves then lost weight and died with typical lesions of hyperkeratosis; in the calves having non-toxic pellets the value fell to and remained at 11 μ g. per 100 ml. In the calves receiving toxic pellets and vitamin A it fell to about 8 μ g. per 100 ml. and rose again to about 16 μ g. per 100 ml. when the toxic pellets were replaced by non-toxic pellets.

For a description of the disorder, see Abst. 1523, Vol. 18. Calves divided into 6 groups of 2 were given a practical ration. After an initial period of 3 weeks the groups were treated as follows: group 1, control, no treatment; 2, sprayed with

0.05 per cent. lindane in mineral seal oil (a petroleum fraction); 3, sprayed with 10.5 per cent. methoxychlor in mineral seal oil; 4, sprayed with 3.2 per cent. lethane and 2.3 per cent. thanine (thiocyanate compounds) in mineral seal oil; 5, X-disease controls receiving by mouth 0.1 g. highly chlorinated naphthalene in maize oil daily for 6 days; 6, sprayed with mineral seal oil only. The X-disease control calves of group 5 developed some of the usual signs of the disease but did not show skin lesions. Those of groups 2, 3, 4 and 6 developed hyperkeratosis, and a consistent, clear-cut drop in the level of vitamin A in the plasma occurred within a week. The fall of vitamin A in the plasma was not so sharp when chlorinated naphthalene was given by mouth. The vitamin A content of the livers showed that reserves had not been depleted at the time of slaughter.—R. J. Ward.

2939

KRUKOVSKY, V. N., TRIMBERGER, G. W., TURK, K. L., LOOSLI, J. K. and HENDERSON, C. R. **Influence of roughages on certain biochemical properties of milk.** *J. Dairy Sci.*, 1954, **37**, 1-9. [New York State Coll. Agric., Cornell Univ., Ithaca.]

All cows were given 10 lb. grain concentrate daily and as much as they could eat of conserved mixed herbage of 4 kinds: early silage, cut 1 June; barn-cured hay, cut 18 June; late silage, cut 10 July, and field-cured hay, cut 10 July. They were given in a design [not specified] each for 5 weeks at a time, to one of 4 groups of 3 cows. At the end of each 5-week period tocopherol, vitamin A and carotene were estimated in the milk. Copper was added to samples of the milk and changes in palatability were recorded during 10 days.

Early silage had the highest tocopherol and carotene content and hay the lowest. The fat of milk produced with early silage had most, and with hay least, tocopherol, vitamin A and carotene.

Oxidised flavour in presence of copper developed most slowly in milk produced with late silage, although it had only two-thirds the tocopherol content of milk produced with early silage. Evidently some protective substances other than tocopherols were present in the more mature roughages. The milk of some cows continued to contain such substances long after the test was discontinued; their origin and mode of action is discussed. Seasonal changes in the herbage might have been concerned.—V. R. Booth.

2940

DAVIES, A. W. and WORDEN, A. N. **The stability of vitamin A in animal feeding-stuffs.** *J. Sci. Food Agric.*, 1954, **5**, 107-112. [Cromwell House, Huntingdon.]

Cod liver oil was mixed into typical feedingstuffs ground to 2 different degrees of fineness, with and without the addition of mineral salts. Portions of each of the 4 mixtures were stored in 9 different ways and vitamin A was estimated with the SbCl_3 reagent every few days for up to 15 weeks. Certain mixtures were cubed and stored.

Loss of vitamin A was greater in a mixture of coarse than of fine particles, but was reduced by cubing. It was much greater in the light than in the dark and was retarded at low temperatures. The loss was greater in open than in closed containers.

Cod liver oil was mixed with separate portions of individual ingredients of the feed to find out which had the greatest effect on the loss. The damaging effect of mineral salts on vitamin A was confirmed and was prevented by treating the mineral mixture with gelatine before adding it to the other ingredients. Yeast hastened the loss slightly. The loss was least in cod liver oil mixed with fishmeal and liver meal. In a few instances observations were made on the loss of carotene, which was usually destroyed more slowly than vitamin A.

The findings are discussed in relation to an extensive review of the literature. The different rates of loss of vitamin A from the synthetic palmitate and from cod liver oil are discussed also.—V. H. Booth.

2941

SIEDLER, A. J. and SCHWEIGERT, B. S. **Vitamin stabilization. Effect of added stabilized animal fats on stability of vitamin A in feeds.** *J. Agric. Food Chem.*, 1954, **2**, 193–195. [Div. Biochem. Nutrit., American Meat Inst. Found., Chicago 37, Ill.]

A typical dry meal for dogs was prepared in which fish liver oil was incorporated directly or dissolved first in pork fat stabilised by addition of butylated hydroxyanisole. Vitamin A was estimated chemically at intervals during storage for a year at room temperature. In a few weeks the curves showing loss of vitamin A diverged, and, after a year, more than half the vitamin was lost from the meal in which the fish liver oil was incorporated directly, and less than half from the meal containing the stabilised fat.—V. H. Booth.

2942

DAMMERS, J. **Stability of carotene in mixed feeds.** *Netherlands J. Agric. Sci.*, 1953, **1**, 245–250. [State Agric. Exp. Stat., Hoorn.]

Dried grass meal and a mixed feed, containing cereals, oilseed residues, mineral salts and 10 per cent. of the dried grass meal, were stored in paper bags. Carotene was estimated weekly. The average weekly percentage loss was 3.01 ± 0.19

from the mixed feed and 4.48 ± 0.29 from the grass meal. In another experiment the mixture contained meatmeal and fishmeal but no by-product of the oil industry. The average weekly percentage loss was 0.87 ± 0.14 from the mixture and 0.81 ± 0.24 from the meal. The first experiment was made in summer, the second in winter, which may explain the great difference in rate of loss. It is concluded that destruction of carotene in dried grass meal during storage is not increased by the presence of other feedingstuffs.

V. H. Booth.

2943

NARAYANAN, K. M., ANANTAKRISHNAN, C. P. and SEN, K. C. **Vitamin A in dairy products. 1. Stability of vitamin A and carotene in ghee fortified with synthetic vitamin A.** *Indian J. Dairy Sci.*, 1953, **6**, 189–195. [Indian Dairy Res. Inst., Bangalore.]

Samples of milk were obtained from 4 cows and 4 buffaloes maintained on two different diets, one including a liberal and the other a small supplement of green grass. Samples of cream were fortified with synthetic vitamin A acetate at 2 concentrations, 45 and 85 I.U. per g., and stored in different containers at 37°C . for 6 months.

After 3 months the loss of vitamin A was less than 3 per cent. in samples stored in glass, aluminium and tin containers but samples stored in mud pots lost 26.8, 59.4 and 94.4 per cent. at the end of 1, 2 and 3 months, respectively. Percentage loss of vitamin A after 6 months amounted to 14.1 for tin containers, 14.5 for aluminium, 14.8 for glass and 100 for mud pots. Fortified cow ghee was more stable, as regards both loss of vitamin A and peroxide development, than fortified buffalo ghee. Stability of vitamin A was not affected by the grass intake or by the level of fortification. The carotene content of cow ghee in glass, aluminium and tin containers remained unchanged for 2 months and then showed losses amounting to 5.6, 12.1, 12.2, and 13.9 per cent. after 3, 4, 5 and 6 months' storage. Cow ghee stored in mud pots showed losses of carotene amounting to 23.9, 53.8 and 95.8 per cent. at the end of 1, 2 and 3 months. Peroxide values were relatively higher at all stages for buffalo than for cow ghee.—I. M. Sharman.

2944

BRESSANI, R., CAMPOS, A. A., SQUIBB, R. L. and SCRIMSHAW, N. S. **Nutritive value of Central American corns. 4. The carotene content of thirty-two selections of Guatemalan corn.** *Food Res.*, 1953, **18**, 618–624. [Inst. Nutrición Central America, Guatemala.]

The β -carotene content of maize grown in Guatemala was estimated by a chemical method. From one site the average for 13 yellow varieties was 1.15 p.p.m. and for 11 white varieties 0.33. In

another area 4 yellow to red varieties averaged 1.57, and 4 white to black 0.14. Tiquisate Golden Yellow averaged 3.3 when grown on lowland sites and 1.8 when grown at 5000 ft.

Cryptoxanthol and other carotenoids were estimated in three varieties, in one (Tiquisate Golden Yellow) by a biological test with chicks, which gave a value for potency of 5.6 p.p.m. Since the β -carotene content accounted for less than half the biological activity, it is concluded that estimation of β -carotene alone is not a satisfactory measure of pro-vitamin A content. Most of the activity not accounted for by β -carotene was due to cryptoxanthol.—V. H. Booth.

BUDOWSKI, P. El aceite de palma (*Elaeis guineensis*) como fuente de vitamina "A" en la alimentacion popular. [Oil of the palm *Elaeis guineensis* as source of vitamin A in the

national diet.] *Arch. venezol. Nutricion*, 1952, **3**, 309–328. [Inst. Nac. Nutrición.] English and German summaries.

In 22 samples of red palm oil grown in the state of Yaracuy there was an average value of 810 μ g. carotene per g. estimated chromatographically. Up to 90 per cent. of the carotene was β -carotene. The crude oil contained about 5 per cent. of free fatty acids calculated as palmitic acid. Loss of carotene during refining was not more than 30 per cent. unless the oil was exposed to temperatures above 160° C. for an hour or longer after neutralisation. Treatment with adsorbent bleaching agents removed much of the carotene, but partial bleaching gave a stable light yellow oil which, when mixed with hydrogenated cottonseed oil, provided a useful cooking fat, acceptable in flavour and consistency and providing a valuable source of carotene for Venezuelan diets.—A. M. Copping.

VITAMIN D

2946

REKLING, E., GJEDDEBÆK, N. F. and STØRLING, E. Penicillinets evne til at forøge virkningen af D-vitamin ved experimental rotterachitis. [Capacity of penicillin to increase the activity of vitamin D in experimental rickets in rats.] *Nord. Med.*, 1954, **51**, 300–301. [A/S Ferrosans Forsøgslab., Copenhagen.] English summary.

Colonies of rats for use in the biological estimation of vitamin D must be uniformly fed on a diet which does not allow storage of vitamin D in the suckling young. When penicillin came to be used for the treatment of gastro-intestinal infections in the colony, results which had been satisfactorily consistent became unreliable, and analysis showed that the young from mothers given penicillin reacted as if they had had more than the amount of vitamin D given. Controlled experiments with graded amounts of vitamin D₃, alone or with 8000 I.U. penicillin given daily by mouth, showed that, as judged by planimetry of the epiphyseal line of the tibia, penicillin approximately doubled the potency of the vitamin. No explanation is offered.

VINET, A. Relations entre les formes nouvelle et ancienne de la vitamine D₃. [Relations between the new and old forms of vitamin D₃.] *C.R. Acad. Sci.*, 1954, **238**, 846–847.

The exact procedure is described for converting into one another classic vitamin D₃ and the new form of vitamin D₃ prepared from cholesterol without ultraviolet irradiation (Absts. 2853, Vol. 23; 346, Vol. 24). Some physical constants of the new substance were measured. It is suggested that classic vitamin D₃, isolated from fish liver oils, may be a product of transformation resulting from energetic treatment with alkali, and that the new substance may be the form of vitamin D₃ naturally active in the organism.—E. M. Hume.

CAUSERET, J. Un nouvel aspect de l'action de la vitamine D sur la croissance. [A new aspect of the action of vitamin D on growth.] *C.R. Acad. Sci.*, 1954, **238**, 160–162.

Further evidence is put forward in support of the author's conclusion that vitamin D does not affect growth only by promoting the retention of Ca (Abst. 349, Vol. 24). Groups of 6 young rats weighing from 60 to 80 g. received a diet containing, per cent., casein 18, arachis oil 9, starch 45, sucrose 24, salt mixture of Hubbel without CaCO₃ 2, agar 2 and vitamins. By adding CaCO₃, diets were constituted containing Ca, per cent., 0.035, 0.055, 0.105, 0.155, 0.255, and 0.455; each diet was given to 2 groups, one receiving 300 I.U. vitamin D₃ per 100 g. diet and one not. For each of 4 successive periods of a week, bodyweight was recorded and Ca retention was measured. The

N.A. and R., July 1954

results showed that on diets poor in Ca, with the same retention of Ca, growth might be much better if vitamin D was present in the diet. The effect was apparent from the beginning of the experiment. It seemed possible that the effect of vitamin D on appetite was important.

CLAASSEN, V. and WÖSTMANN, B. S. J. **The uptake of injected radioactive phosphorus in the skeleton of the growing white rat. 2. The effect of calciferol on the rapid uptake of ^{32}P by rachitic and control animals. 3. The metabolism of skeletal ^{32}P in experiments of longer duration, performed with rachitic and control animals.** *Biochim. biophys. Acta*, 1953, **12**, 577-583; 1954, **13**, 48-53. [Lab. Physiol. Chem., Netherland Inst. Nutrit., Municipal Univ., Amsterdam.] French and German summaries.

2. Rats were maintained from weaning on a modification of Steenbock and Black's diet containing, per cent., Ca 1.2 and P 0.3. Some received also 6 I.U. vitamin D_2 daily. After rickets had developed, half the rachitic and half the protected rats received by mouth 3000 I.U. vitamin D_2 , 5 or 72 hr. before intravenous injection of from 15 to 20 μC . ^{32}P as Na_2HPO_4 . The rats were killed 5 or 60 min. after the injection of ^{32}P , and the femur and plasma were analysed (for details of procedure, see Abstr. 1735, Vol. 24).

Five min. after injection, the content of ^{32}P in the femur of rachitic rats given vitamin D 72 hr. previously was slightly greater than of those not given vitamin D, but the difference was not significant; there was no difference between protected rats previously given and not given vitamin D. Sixty min. after injection of ^{32}P , the content of ^{32}P in the femur of rachitic rats given vitamin D 72 hr. previously was much greater than in those not given vitamin D. There was again no difference between protected rats. Administration of vitamin D 5 hr. before injection of ^{32}P had no detectable effect. It had also no effect on the value for inorganic P in the plasma of rachitic rats, which, however, was much increased by vitamin D given 72 hr. previously. In protected rats the values were unchanged.

It is concluded that the uptake of ^{32}P into the bone by exchange is not greatly influenced by administration of vitamin D, but that the uptake caused by increased calcification is much heightened.

3. Rats were maintained as above on Steenbock and Black's rachitogenic diet with or without 6 I.U. vitamin D daily. They were injected subcutaneously with ^{32}P as Na_2HPO_4 , and the increase in the amount of ^{32}P in the tibia during 14 days was

compared with the increase to be expected from skeletal accretion alone. For this purpose one hind leg was removed at the knee from young rats weighing about 120 g., 3 days after the injection of ^{32}P . Fourteen days later the rats were killed and the tibia from the other hind leg was taken. P and ^{32}P were estimated in each tibia and every 4 or 5 days in the plasma. The difference in phosphate content between the two tibiae combined with the specific activity (activity per mg. P) of the plasma inorganic phosphate was used to calculate the increase of the ^{32}P content of the bone caused by skeletal accretion during the experimental period. This value was compared with the difference in ^{32}P content actually found. Although the amount of P and ^{32}P taken up by the rachitic bone was less than by the non-rachitic bone, the behaviour of the two did not differ greatly. The increase in content of ^{32}P in the bone during the experiment was much less than would be expected from the action of skeletal accretion alone, and it is concluded that considerable loss of ^{32}P occurred by exchange with the plasma of radio-active for inactive material throughout the experimental period. The gain of ^{32}P by skeletal accretion was thus counteracted by loss through exchange with the plasma.—E. M. Hume.

JOVANOVIĆ, M., TOMIĆ, V., KENTERA, D. and VUČO, J. Influence de la vitamine D sur le métabolisme du phosphore introduit par voie parentérale. [Effect of vitamin D on the metabolism of phosphorus given parenterally.] *Acta vet., Belgrade*, 1953, **3**, 117-126. [Inst. Physiol., Fac. Vet., Univ. Belgrade.] In Serbian: French summary.

Twenty-five rats in 3 groups were injected twice, with a 24-hr. interval, with 0.2 ml. Vigantol (vitamin D_2). The next day the 3 groups and 25 untreated rats received from 1 to 2 mC. radio-active phosphorus as Na_2HPO_4 . The concentration of P in the blood was estimated from the radio-activity of the blood, after 6 hr. in the first group, after 24 hr. in the second group and after 10 days in the third group.

In the first group the percentage of the radio-active P recovered in 1 ml. blood was 0.154 against 0.120 in the group not treated with vitamin D. In the second group the figures were 0.121 against 0.129 and in the third group 0.040 against 0.037.

It is concluded from the values for the first group that vitamin D stimulates, not only intestinal, but also parenteral absorption of P, and from the values for the second and third groups that large amounts of vitamin D do not cause retention of larger amounts of P in the blood or affect the intensity of P exchange between the blood and tissues.—S. Pribićević (Yugoslavia).

2952

STEENBOCK, H. and BELLIN, S. A. **Vitamin D and tissue citrate.** *J. Biol. Chem.*, 1953, **205**, 985-991. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Citrate was estimated in the blood, bone and tissues of female rats 5 weeks old, kept for from 8 to 36 days on cereal-free, semi-synthetic diets, low in P, or normal in P and half normal in Ca, or low in Ca, or low in Ca, P and Mg, or with no inorganic addition except 0.4 per cent. NaCl. The diets were given with and without addition of from 75 to 150 I.U. vitamin D every 3 days. In some tests NaHCO_3 was given to promote alkalosis.

With the rachitogenic diet low in P and with the non-rachitogenic diet normal in P and half normal in Ca, the citrate content of the blood, heart, kidneys, small intestine and bone was higher when vitamin D was given, but in the liver there was no difference. The citrate values were highest with a low intake of P, but the increases caused by vitamin D were greatest with an adequate supply of P. Alkalosis induced with NaHCO_3 had no effect on the blood value for citrate or on the action of vitamin D in raising it. The changes in the blood value for citrate induced by vitamin D could not be correlated with changes in the blood values for Ca and P. No evidence was found that the amount of citrate in bone was reduced in rickets; the amount seemed rather to be related to the animal's state of Ca nutrition. Administration of bicarbonate did not increase bone citrate. The increased urinary excretion of citrate previously observed after giving vitamin D (Abst. 338, Vol. 22) is considered to result from the increased accumulation of citrate in the tissues.

STEENBOCK, H., KRIEGER, C. H., WIEST, W. G. and PILEGGI, V. J. **Vitamin D and intestinal phytase.** *J. Biol. Chem.*, 1953, **205**, 993-999. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Groups of 5 Leghorn chicks, 2 days old, were fed, with or without vitamin D, on a practical poultry ration containing cereals or on a highly rachitogenic diet of, per cent., yellow maize 58, wheat middlings 25, casein 12, NaCl 1, $\text{Ca}_3(\text{PO}_4)_2$ 2, dried yeast 2, and $\text{MnSO}_4 \cdot 4\text{H}_2\text{O}$ 0.02. After from 4 to 8 weeks the chicks were killed; the tibiae were removed for ash analysis and the small intestine for phytase estimation. The intestine was washed, macerated and left to autolyse for 48 hr.; it was centrifuged and the centrifugate, suitably buffered, was incubated for 48 hr. at 37° C. with Na phytate as substrate. Inorganic P was estimated before and after incubation. With both diets vitamin D increased the percentage

bone ash from about 30 to about 40, and the units of phytase by from 50 to 100 per cent.

Similar tests were made on the 10 in. of the small intestine nearest to the stomach of rats given different diets with and without cereals, some of them rachitogenic, and with or without small or large doses of vitamin D. With vitamin D, the amount of intestinal phytase was always greater than without, whether the rats were rachitic or not, and whether the diet contained cereals or not. There was apparently no relation between the severity of the rickets and the degree of activity of intestinal phytase.—E. M. Hume.

HANSSLER, H. Experimentelle Untersuchungen über das Verhalten der Nebenschilddrüse bei diätetisch erzeugter Rachitis und Tetanie. [Experimental studies on the behaviour of the parathyroid glands in rickets and tetany of dietary origin.] *Ztschr. ges. exp. Med.*, 1954, **123**, 91-100. [Kinderklin., Univ. Tübingen.]

Thirty rats weighing about 50 g. were kept in the dark on a complete diet of milk and bread, or on McCollum's rachitogenic diet No. 3143 low in P with or without vitamin D, or on a diet low in Ca with or without vitamin D. The rats were killed at intervals of up to 28 days. Ca and inorganic P were estimated in the blood, and the activity of the parathyroid glands was assessed by measuring the size of the cell nuclei in histological preparations. In a comparison of the rats having the complete diet, McCollum diet, and McCollum diet with vitamin D₃, the serum Ca values increased progressively in that order, and the size of the parathyroid nuclei correspondingly decreased.

In another experiment 38 rats were used. When the McCollum diet without vitamin D₃ was compared with the diet low in Ca with and without vitamin D₃, the blood values for the rats on the diet low in Ca without vitamin D₃ fell to just below 6 mg. Ca per 100 ml., and there was an increase in the size of the parathyroid nuclei; both effects were considerably modified towards normal when vitamin D₃ was added to the diet low in Ca. The values for the rats having the McCollum diet were as in the first experiment.

It is concluded that the activity of the parathyroid glands, as assessed by the size of the nuclei, was negatively related to the value for serum Ca.

MORETTI, I. La muscolatura striata nel rachitismo sperimentale. [Striated muscle in experimental rickets.] *Acta vitaminol.*, 1953, **7**, 240-245. [Ist. Anat., Univ. Pavia.] French, English, German and Spanish summaries.

N.A. and R., July 1954

Twenty rats weighing from 24 to 30 g. were maintained on the rachitogenic diet 2964 of Steenbock and Black. Half of them died in the first 3 weeks, before the appearance of rickets. Of the remainder, some died and some were killed at intervals of up to 45 days with marked skeletal changes. The resistance of the muscles to traction was almost the same in the rachitic and normal rats. Examined histologically, the fibres of the skeletal muscles were attenuated and the nuclei appeared to be nearer together. In the myocardium there was no difference.—E. M. Hume.

2956

EWER, T. K. **Vitamin D requirements of sheep.** *Austral. Vet. J.*, 1953, **29**, 310-315. [Vet. Sch., Univ. Queensland.]

In this review the etiology of rickets is discussed with special reference to sheep. The vitamin D requirement is conditioned by the amount of sunshine, the type of grazing and the amounts of Ca and P in the diet, and at the moment cannot be accurately assessed.—D. Duncan.

2957

FRANKLIN, M. C. **Vitamin D requirement of sheep with special reference to Australian conditions.** *Austral. Vet. J.*, 1953, **29**, 302-309. [Div. Animal Health Prod., C.S.I.R.O., McMaster Animal Health Lab., Sydney.]

In Tasmania there are about 18 weeks in winter when the sun's height does not exceed 35°, the altitude necessary for effective ultraviolet irradiation.

In 1947, 2 groups of 25 cull Corriedale weaned lambs grazed green oats for 15 weeks from May to August. One group received a subcutaneous injection of one million I.U. vitamin D₂ in May and in July. No difference was observed until July, but in the last 7 weeks 9 untreated lambs lost weight and 4 ceased to grow, while the treated animals continued to gain. The untreated animals showed decreasing values for serum Ca and inorganic P, and 7 developed clinical rickets. Similar results were obtained in New South Wales in 1948 and in Tasmania in 1949, but in another experiment in 1947 and in a series in 1948 there was no significant benefit to the lambs treated with vitamin D₂; the lack of difference is ascribed to differences in the grazing conditions and the weather.

The vitamin D requirements of weaned lambs and their response to vitamin D under field conditions are considered to be uncertain. Supplements are likely to be of most value when the lambs graze green crops in winter, when the grazing is good and the weather bad, and when the lambs start the winter in poor condition.—D. Duncan.

2958

GREEN, R. J. **Some field observations on the effect of vitamin D supplements in sheep.** *Austral. Vet. J.*, 1953, **29**, 316-324 (with discussion 324-325). [Animal Health Serv., Dept. Agric., Launceston, Tasmania.]

The results are described of a number of field experiments in Tasmania in which the effect of giving sheep vitamin D₂ or D₃ by subcutaneous injection was disappointing. Sheep with clinical rickets responded well to vitamin D₂, but when rickets was not apparent there was little advantage from giving vitamin D. The same was usually true for calves also, though with both sheep and calves the treated animals sometimes had a better appearance than the untreated and in one experiment treated calves gained more weight than untreated.

Despite the rarity of dramatic response, vitamin D is considered a "cheap form of insurance" against rickets for grazing sheep in winter.

D. Duncan.

2959

DUNLOP, G. **Rickets in sheep.** *Nature*, 1954, **173**, 453. [W. Scotland Agric. Coll., Auchincruive, Ayr.]

In Ayrshire, in December 1951, of 38 ram hogs reared on low ground pasture from 4 months of age, 20 were given a single oral dose of 2 million I.U. vitamin D₂, and 18 were left untreated. Within a month the blood serum mean values, in mg. per 100 ml., for the treated and untreated, respectively, were for Ca 11.3 and 6.7, and for P more than 5 and less than 4. In spite of treatment, however, rickets began to appear, and in February 1952 all the animals were given 2 million I.U. vitamin D₂ with completely satisfactory results, normal health and growth ensuing. It is recommended that a large dose of vitamin D₂ be given to all young rams twice in the winter to ensure protection against "bent-leg".—E. M. Hume.

NEUWEILER, W. Vitamin D-Hypervitaminose und Schwangerschaft. [**Vitamin D₂ excess and pregnancy.**] *Internat. Ztschr. Vitaminforsch.*, 1954, **25**, 203-204. [Frauenklin, Univ. Berne.] English and French summaries.

Guineapigs having a normal diet were given, daily, 1200 I.U. vitamin D₂. In comparison with other animals having the same diet without added vitamin D, the sexual cycle was much disturbed and the production of young delayed; in the course of 3 litters, the number of young increased from 3 or 4 to 5, and the mortality of the young increased to 48 per cent. from 5. No toxic effect was seen except on the reproductive system.

E. M. Hume.

2962

POLEMANN, G. and FROITZHEIM, G. Tierexperimentelle Untersuchungen zur Therapie der D₂-Hypervitaminose. [**Animal experiments on treatment of vitamin D₂ excess.**] *Ztschr. Vitamin-, Hormon- Fermentforsch.*, 1952-53, **5**, 329-357. [Hautklin., Univ. Cologne.] French and English summaries.

Mice weighing from 17 to 23 g. were maintained on a normal diet and given a single peritoneal dose of 5 mg. vitamin D₂. Two days later the material to be tested for its protective action was given. The animals died or were killed, and the kidneys, heart, liver, lungs, and aorta were removed. Pre-

liminary experiments showed sesame oil to be the most suitable solvent for the vitamin, and 5 mg. vitamin D₂ to be a dose which caused death in 75 per cent. of the mice within 17 days. The substances tested, given at 2-day intervals from the 2nd to the 14th day, were, in mg. per kg. body-weight, Cystein-Hormodyn (Nordmark) 75; Methionin-Thiomedon (Homburg) 1000; 2:3-Dimercaptopropanol-Sulfactin (Homburg) 50; N-Acetylcysteamine 50; N, S-Diacetyl-cysteamine 50; Rutin-Rutinon (Rheinchemie) 250. Cortisone was given to some mice in a daily dose of 10 mg. per kg. bodyweight after they had lost up to 6 g. weight. No evidence of protection by any of the substances was obtained from the survival time or the histological changes in the organs.

POLISTER, B. H. **Nitrosation method of determining d-γ-tocopherol.** *Anal. Chem.*, 1954, **26**, 407-408. [Sch. Med., Univ. California, Los Angeles.]

A solution of d-γ-tocopherol in dimethoxyethane was treated with acetic acid and sodium nitrite solution to form the nitroso-derivative. Potassium hydroxide was added to form the red derivative, which was then extracted with isooctane. The absorption maxima of this solution at from 450 to 350 mμ. in the visible region and from 340 to 280 mμ. in the ultraviolet region were measured with a Cary recording spectrophotometer; either of them was used for the estimation. The values obtained from a blank prepared in the same manner was subtracted from the reading. The colour was stable for 1 hr. in absence of daylight.—R. J. Ward.

2965

EGGITT, P. W. R. and WARD, L. D. **The chemical estimation of vitamin-E activity in cereal products. 1. The tocopherol pattern of wheat-germ oil.** *J. Sci. Food Agric.*, 1953, **4**, 569-

579. [Spillers, Ltd., Central Lab., Station Rd., Cambridge.]

Complete experimental details are given for estimating the individual tocopherols in wheat germ oil. The reverse phase paper chromatographic method as first described by Brown (Abst. 1525, Vol. 23), and later modified by the present authors (Abst. 4165, Vol. 23) was used for separating the tocopherols. Detailed instructions are given for removing sterols and for preparing the Floridin earth column for removal of carotenoids.

The mean tocopherol content of an ether extract of freshly milled wheat-germ meal was 2990 μg. per g. with 97 per cent. recovery of added tocopherol. The tocopherol percentage composition was origin spot 14.2, α-tocopherol 48.8, β-tocopherol 28.0 and fast spot 9.0, with a chromatogram recovery of 100 per cent. Purified ethyl ether as solvent gave an oil with a slightly higher tocopherol content than cyclohexane. After 2½ hours' extraction all the tocopherol was extracted by ether solvent and continuation of extraction gave a yield of oil which was larger but less potent.

It is suggested that the fast spot is probably 5-methyltocol or ε-tocopherol.—R. J. Ward.

2966

FARBER, M. C., MILMAN, A. E. and MILHORAT, A. T. Vitamin E-Aktivität einiger Tocopherolderivate und verwandter Substanzen. Ein Beitrag zur Kenntnis struktureller Voraussetzungen für biologische Aktivität. [Vitamin E activity of some tocopherol derivatives and related substances; a contribution to the study of the structural conditions for biological activity.] *Hoppe-Seyler's Ztschr.*, 1953, **295**, 318-323. [Dept. Psychiat., Cornell Univ. Med. Coll., New York.]

Rabbits were used to assess the antidystrophic action of several related compounds of α -tocopherol and α -tocopherylquinone. The compounds were administered by mouth or parenterally in sesame oil or in one case in a 1 : 9 solution of ethanol and propylene glycol, and were active in single doses of the amounts shown, in mg.: *dl*- α -tocopherol 5, α -tocopheryl quinone 20, α -tocopheryl hydroquinone 5, tocopheramine 20, tocopheroxide 30, trimethylphytylbenzoquinone 50, trimethyl dihydrophytyl benzoquinone 100 and mercaptotocopheryl acetate 100. α -Tocopherylorthoquinone was not active in a dose of 100 mg. daily and thiotocopheryl acetate was not active when given for 15 days in a dose of 20 mg. daily.

The structural conditions for biological activity are discussed.—R. J. Ward.

2967

MACKENZIE, J. B. and MACKENZIE, C. G. Vitamin E activity of alpha-tocopherylhydroquinone and muscular dystrophy. *Proc. Soc. Exp. Biol. Med.*, 1953, **84**, 388-392. [Div. Chem. Embryol., Univ. Colorado Sch. Med., Denver.]

α -Tocopherylhydroquinone, which is known to be effective against muscular dystrophy in rabbits (Abst. 1647, Vol. 20), was injected in the form of its disuccinate daily or every second or third day into the tail vein of pregnant rats maintained on a diet deficient in vitamin E. Even with total amounts of 128 mg. resorption of the foetuses was not prevented. When single doses of up to 100 mg. of α -tocopherylhydroquinone or its disuccinate were injected into dystrophic rabbits no increase in the concentration of tocopherol in the blood plasma could be detected 24 hr. later. α -Tocopherylhydroquinone appears therefore to be active to prevent muscular dystrophy without being converted to α -tocopherol. *dl*- α -Tocopherol always prevented foetal resorption in a dose of 3 mg. when a total dose even of 152 mg. α -tocopherylhydroquinone succinate had been without effect in the same animals.—T. Moore.

MILMAN, A. E. and MILHORAT, A. T. Metabolic patterns in experimentally induced muscular dystrophy. *Proc. Soc. Exp. Biol. Med.*, 1953, **84**, 654-660. [Dept. Psychiat., Cornell Univ. Med. Coll., New York.]

Young rabbits were kept on a diet deficient in vitamin E or were given daily injections of cortisone, and the biochemical abnormalities associated with the muscular dystrophy produced were compared. After deprivation of vitamin E for 15 days, creatine, K and Ca were greatly increased in the urine, but Na was much reduced. Cortisone caused even greater excretion of creatine, K and Ca, but the clinical signs of muscular dystrophy were less severe. Small doses of pituitary growth hormone partly counteracted the effect of cortisone, but large doses exacerbated the abnormalities. When administered in vitamin E deficiency, the growth hormone had little effect, except to increase N retention for a few days. Both cortisone and the growth hormone caused glycosuria, and when they were given together their effects were additive.—T. Moore.

BACIGALUPO, F. A. and LUECKE, R. W. Some mineral changes in the skeletal and heart muscles of vitamin E deficient lambs. *J. Animal Sci.*, 1954, **13**, 245-248. [Michigan Agric. Exp. Stat.]

The skeletal and heart muscles of lambs in normal health, deprived of vitamin E, or given a curative dose of vitamin E, were analysed for Na, K, Ca, Mg, and P, which were in mg. per 100 g. wet muscle : Na 91, 159, 128 ; K 287, 199, 262 ; Ca 7, 42, 9 ; Mg 31, 22, 20 and P 268, 247 and 268, respectively, for skeletal muscle, and for heart

muscle: Na 120, 144, 225; K 226, 182, 295 mg.; Ca 6, 23, 9; Mg 28, 19, 25 and P 261, 343, 250 mg., respectively. It will be seen that the Ca content of the skeletal muscle and the P content of the heart muscle of vitamin-E-deficient lambs were higher than those of the controls.

CURTO, G. M. Ricerche sull'avitaminosi E sperimentale della cavia maschio. [**Experimental vitamin E deficiency in the male guineapig.**] *Acta vitaminol.*, 1954, **8**, 7-10. [Lab. Anat. Fisiol., Fac. Agrar., Univ. Milan.] French, English, German and Spanish summaries.

Twenty male guineapigs weighing about 300 g. were given a diet of, per cent., skimmed milk powder 27, bran 16, chaff 22, dextrin 12, linseed cake 5, coconut cake 5, groundnut cake 4, and brewer's yeast 2, all treated with ultraviolet light to destroy tocopherols, mineral salts 2, and rancid fat 5; 2 drops tunny liver oil and 5 mg. vitamin C were given daily. Ten guineapigs received normal diet. After 180 days the animals were killed, and histological examination showed the testicular changes characteristic of vitamin E deficiency in rats.—E. M. Hume.

2973

DAVIS, C. L. and GORHAM, J. R. **The pathology of experimental and natural causes of "yellow fat" disease in swine.** *Amer. J. Vet. Res.*, 1954, **15**, 55-59. [Branch Pathol. Lab., Bur. Animal Indust., U.S. Dept. Agric., Denver, Colo.]

Histological studies were made on the yellowish fatty tissues and visceral organs of 10 pigs which had been fed experimentally on fish scraps. The animals did not thrive and some of them died. The fat only from 4 carcasses which had been condemned at slaughter-houses was examined also. Discolouration of the fat was accompanied by a fishy odour of the flesh. In the interstices of the adipose tissues of both experimental and condemned animals, microscopical examination revealed the presence of globules of foreign fat, some of which were acid-fast. The acid-fast material was found also in the Kupffer cells of the liver. Supplements of vitamin E allowed the pigs to thrive, and the discolouration of fat was reduced but not completely prevented by the amounts given.

HOVE, E. L. **The toxicity of tri-*o*-cresyl phosphate for rats as related to dietary casein level, vitamin E and vitamin A.** *J. Nutrition*, 1953, **51**, 609-622. [Dept. Animal Husb., Agric. Exp. Stat., Alabama Polytech. Inst., Auburn.] The growth of rats given a diet deficient in vitamin E and containing 20 per cent. casein was

slowed by the addition of 0.1 per cent. tri-*o*-cresyl phosphate. The cresyl phosphate also further decreased the subnormal growth obtained when the diet contained only 10 per cent. casein, but with 60 per cent. casein there was no depression. The depression of growth caused by cresyl phosphate or deficiency of protein was only partly corrected by 1 or 10 mg. α -tocopherol daily.

The composition of the fat in the liver, brain and carcass of selected rats was studied by several methods, including spectroscopic estimation of conjugated dienes as a measure of peroxide formation. Cresyl phosphate increased the conjugated dienes and other signs of oxidation, but tocopherol or a larger supply of casein had the opposite effect. Cresyl phosphate decreased the concentration of tocopherol in the tissues, and the accumulation of vitamin A reserves in the liver of animals given β -carotene or vitamin A acetate.

In vitro, the presence of cresyl phosphate, carbon tetrachloride, pyridine or pentachloronaphthalene increased the destruction of carotene by fat peroxides. Limited data suggested that chloronaphthalene poisoning in cattle is associated with reduction in the concentration of vitamins A and E in the plasma.—T. Moore.

RICHERT, D. A. and WESTERFELD, W. W. **Vitamin E deficiency and xanthine oxidase in rabbits.** *Proc. Soc. Exp. Biol. Med.*, 1953, **84**, 468-470. [Dept. Biochem., Med. Coll. State Univ. New York, Syracuse.]

Rabbits were given a diet deficient in vitamin E until they developed muscular dystrophy. Others were given an adequate diet of chow, or the deficient diet with supplements of mixed tocopherols. Estimation of xanthine oxidase in the liver in the presence or absence of methylene blue showed the activity to be much greater in the deficient than in the normal animals. The slight activity in the intestines was not increased in vitamin E deficiency, and no activity was detected in the heart, lung, kidney, spleen, brain or skeletal muscle of any animals. The content in the tissues of Mo, which has been reported to be concerned in the xanthine oxidase system, was influenced by varying the Mo content of the diet, but not by the presence or absence of vitamin E.—T. Moore.

FORBES, M., BARNES, L. A., MOEKSI, H. and GYÖRGY, P. **Excretion of ether-soluble acids by rats on necrogenic diet with and without supplements of antibiotics.** *Proc. Soc. Exp. Biol. Med.*, 1953, **84**, 162-165. [Dept. Paediat., Sch. Med., Univ. Pennsylvania, Philadelphia.]

Weanling rats were kept on a diet designed to produce liver necrosis. Supplements of aureomycin, penicillin or vitamin E caused no quantitative alteration in the urinary excretion of ammonia, urea N, creatinine, hippuric acid or *p*-aminobenzoic acid. Most rats on the unsupplemented diet died of liver necrosis after between 30 and 60 days, but in the few survivors and in the animals receiving vitamin E the urinary excretion of ether-soluble acids was significantly higher than in the rats treated with aureomycin or penicillin. Chromatograms showed that methylmalonic acid formed the largest part of the total ether-soluble acid in the untreated or vitamin-E-treated animals, but in rats treated with antibiotics $\alpha\alpha$ -dimethylsuccinic acid and an unidentified acid with $R_F = 0.80$ formed the largest part of the acid excretion, with a smaller proportion of methylmalonic acid. An unidentified acid with $R_F = 0.45$ occurred in the urine of almost all the rats treated with antibiotics and of a few untreated or treated with vitamin E.—M. B. Richards.

MASURE, R., DE STOOP, P. and SOLVAY, H. **L'action de la vitamine E sur le temps de saignement du lapin. [Action of vitamin E on bleeding time in the rabbit.]** *Rev. belg. Pathol. Méd. exp.*, 1953, **23**, 102-110. [Clin. Méd. A., Univ. Louvain.]

Repeated observations were made on the times taken for the fine blood vessels of rabbits' ears to stop bleeding under water after experimental cuts. The administration of disodium α -tocopheryl phosphate by mouth or intramuscular injection decreased the time of bleeding. α -Tocopheryl acetate also, when injected, accelerated haemostasis, but by mouth prolonged bleeding. When intravenous injections of calcium gluconogalactogluconate were given in addition to tocopherol, the time of bleeding 15 min. after the last injection of Ca salt was always prolonged. Irregular results were obtained when the observations were postponed for longer after the injection of the Ca salt.

MALDONADO VELIZ, M. A. **Acción de los tocoferoles sobre la ascorbinemia en conejos. [Effect of tocopherols on blood ascorbic acid in rabbits.]** *An. Fac. Farm. Bioquim., Lima*, 1952, **3**, 296-311. [Lab. Farmacol., Univ. Lima.]

Changes in blood ascorbic acid, estimated by indophenol titration with a colorimeter, were studied in rabbits receiving from 50 to 1200 mg. α -tocopherol given orally or by intraperitoneal injection. In general, male rabbits showed a greater increase in blood ascorbic acid than females. The increase was greater in both sexes when the tocopherol was given orally. The results are shown in a series of graphs from which it can be deduced that the effect of a dose of tocopherol on the values for blood ascorbic acid reached its maximum within 24 hr., after which the values fell to the original level.

HALEY, T. J., McCULLOH, E. F. and McCORMICK, W. G. **Influence of water-soluble vitamin E on survival time in irradiated mice.** *Science*, 1954, **119**, 126-127. [Div. Pharmacol., Atomic Energy Project, Sch. Med., Univ. California, Los Angeles.]

Groups of mice, of bodyweight about 20 g., were injected intramuscularly with saline, or with water-soluble preparations containing 0.5, 1.0, 2.0 or 3.18 mg. α -tocopherol. The animals were submitted to lethal X-ray exposure on a single occasion and the injections were continued daily until most of them had died. Tocopherol in the two lower doses had no effect on the survival time of the mice but,

contrary to expectation, significantly shortened life in the two higher doses. [The possible toxicity of the higher doses without X-ray exposure does not appear to have been studied.]-T. Moore.

2983

BEILER, J. M., SWAYNE, V. R., MENAKER, J. and MARTIN, G. J. **Anti-fertility activity of *Pisum sativum*.** *Exp. Med. Surg.*, 1953, **11**, 179-185. [Res. Labs., Nat. Drug Co., Philadelphia, Pa.]

In view of the reports of Sanyal (Absts. 288, Vol. 21; 2621, Vol. 22), an investigation into the effects of *Pisum sativum* was made on white mice of the Webster strain. Ground peas were mixed with Purina chow as 10, 20 or 30 per cent. and the diets were given for a week before mating. With 30 per cent. the diet proved toxic, and 6 of 10 male mice and 4 of 20 female died within 12 days. Changes were found in the reproductive organs of the surviving males. With 20 per cent. of peas, 14 out of 20 females produced normal young, and with 10 per cent., 15 of 20 produced litters. Vitamin E was added to the diet of 8 of the remaining 16 females having 30 per cent.; after 28 days no pregnancy occurred and 3 of the 8 without vitamin E had died. All

the animals were killed and there was increased vascularity of the uterus and ovaries in those without vitamin E. Those having vitamin E showed no abnormality of the uterus or ovaries. In tests with ether extracts of peas dissolved in arachis oil 6 pregnancies were obtained from 9 mice, while of 9 receiving only the arachis oil 8 became pregnant. The problem of separating the antifertility effect from the toxic effect is discussed.

ISLER, O., RÜEGG, R., STUDER, A. and JÜRGENS, R. Konstitutionsspezifische Wirkung von Vitamin K₁ und Analogen gegen Cumarin-Verbindungen. [Chemical constitution and the antagonism of vitamin K₁ and its analogues to coumarol compounds.] *Hoppe-Seyler's Ztschr.*, 1953, **295**, 290-309. [Wissenschaftl. Lab., Hoffmann-La Roche Co. A.G., Basle.]

A brief note is given of the synthesis and chemical nature of 24 analogues of vitamin K which were tested for their capacity to shorten prothrombin time in rabbits given dicoumarols or promote survival in rats given toxic doses of dicoumarol derivatives. Certain of the vitamin K compounds and of the dicoumarols appeared to have different effects for rabbits and rats. Vitamin K₁ was active for both species against all types of dicoumarol. The activity of other vitamin K analogues depended on the structure of the molecule. The presence of a side-chain like that in vitamin K₁ or K₂ gave fullest activity. The presence of methyl groups and double bonds in the side-chain helped the activity, but appeared not to be essential; short side-chains of less than 8 C atoms gave inactive compounds.

MARTIUS, C. and NITZ-LITZOW, D. Über den Nachweis einer Wirkung von Vitamin K₁ *in vitro* auf die oxydative Phosphorylierung. [Demonstration of an action of vitamin K₁ *in vitro* on oxidative phosphorylation.] *Biochim. biophys. Acta*, 1954, **13**, 289-290. [Physiol. Chem. Inst., Univ. Würzburg.]

Oxidative phosphorylation *in vitro* was low in liver mitochondria from chicks deprived of vitamin K. A marked increase occurred when vitamin K₁ in a concentration of 10⁻⁵ or 10⁻⁶, was added to the mitochondria, but not when 2-methyl-1:4-naphthaquinone was added. If chicks were given 50 µg. vitamin K₁ orally 24 hr. before they were killed, addition of the vitamin to mitochondria preparations had no effect on phosphorylation.

QUICK, A. J., HUSSEY, C. V. and COLLENTINE, G. E. (Jr.) **Vitamin K requirements of adult dogs and the influence of bile on its absorption from the intestine.** *Amer. J. Physiol.*, 1954, **176**, 239-242. [Dept. Biochem., Sch. Med., Marquette Univ., Milwaukee, Wis.]

Vitamin K requirement was studied in dogs after cholecystonephrostomy. The exclusion of

N.A. and R., July 1954

bile from the intestine prevented absorption of vitamin K. The deficiency could be overcome by giving very large amounts of bile with food or by injection of vitamin K. A normal level of prothrombin could be maintained with a daily injection of 0.5 μ g. vitamin K₁ per kg. bodyweight. Doses of 5000 μ g. vitamin K₁ given orally raised the prothrombin value in the blood even when no bile was administered.—A. M. Copping.

KOSER, S. A. and THOMAS, J. L. Activity of some vitamin derivatives and related compounds for oral lactobacilli. *J. Infect. Dis.*, 1953, **93**, 192-199. [Walter G. Zoller Mem. Dent. Clin., Chicago, Ill.]

Growth was estimated turbidimetrically of 15 strains of oral lactobacilli, 10 of the homofermentative type, 5 of the heterofermentative type, and of *L. casei*, *L. arabinosus*, *L. fermenti* and *L. acidophilus* from laboratory stock, on a casein-digest medium previously described (Abst. 295, Vol. 21) in which indispensable, individual vitamins were replaced by a derivative or related compound.

Of the biotin substitutes, oxybiotin in small amounts supported vigorous growth, the response being a little slower on occasion than to biotin. Desthiobiotin, even in large amounts, gave a slow and poor response in about a third of the cultures and none in the others; norbiotin and biotinol had a thousandth of the activity of biotin but could support good growth; homobiotin was much less active.

The derivatives of nicotinic acid, which included isonicotinic, picolinic and quinolinic acids, were almost inactive. Nicotinylnitrate, monoethylamide and

to a less extent the diethylamide, and 3-pyridine methanol in fairly large amounts, supported moderate growth of most strains. It is, however, considered possible that these substances were contaminated with nicotinic acid. Four other derivatives and two pyrazine carboxylic acids were completely inactive.

Pantothenic acid could not be replaced by Na pantoate, β -alanine or pantolactone, separately or in combination, or by panthenol, which sometimes inhibited growth.

Only the heterofermentative group required vitamin B₁ for growth, and for most of them the thiazole moiety supported growth which was slower but ultimately comparable with that promoted by the vitamin. The pyrimidine moiety did not support growth.

Where a vitamin substitute supported growth the pH of the cultures was lowered to an extent comparable with the degree of turbidity.

ALMQUIST, H. J. Application of the law of diminishing returns to estimation of B-vitamins requirements for growth. *Poultry Sci.*, 1953, 32, 1001-1003. [Grange Co., Modesto, Calif.]

It is suggested that the vitamin requirements of young animals can be calculated from feeding experiments with graded amounts of the vitamin more accurately by plotting the response against the logarithm of the dose than against the dose itself.

In the examples shown the response at amounts below the requirement was linear, and the point of intersection with a horizontal line through the maximum response then gave a more exact estimate of the requirement than inspection of the direct response curve usually plotted.

ŁUCZAKOWA, M. J. Wpływ żywienia krów na zawartość witamin B₁ i B₂ w mleku. [Influence of feeding on the vitamin B₁ and riboflavin content of milk.] *Rocz. Państwowego Zakł. Hig.*, 1953, No. 4, 513-520. Russian and English summaries.

The vitamin B₁ and riboflavin content of 115 samples of milk, estimated at different seasons of the year, was, respectively, in μ g. per cent.,

N.A. and R., July 1954

winter 46.2 and 129.9, summer 54.7 and 156.2, autumn 64.4 and 166.9. It is suggested that 1½ pints of milk daily is sufficient to meet the riboflavin requirement of a 1-year-old infant and the vitamin B₁ requirement also during the summer and autumn, but only 25 per cent. of the requirement during the winter months. (From summary.) J. S. Thomson.

2998

HOEFLAKE, H. **An investigation into the riboflavin, nicotinic acid, pantothenic acid and biotin contents of Dutch market milks, determined by the microbiological method.** *Nederlands Melk Zuiveltijdschr.*, 1953, 7, 227-239. [Lab. Inspectorate Law Commodities, Dordrecht.] Dutch summary.

Samples of bulked morning and evening milk were collected at regular intervals from July 1948 to July 1949 in the districts of Alblasserwaard and the Isle of Dordrecht. Riboflavin, nicotinic and pantothenic acids, and biotin were estimated in the raw and pasteurised milk and occasionally in sterilised milk or buttermilk, by the microbiological methods described by Barton-Wright (*Practical methods for the microbiological assay of the vitamin B complex and essential amino acids*, Ashe Laboratories, London, 1946).

About 10 per cent. of the riboflavin content of milk was bound, probably to protein, and was liberated at pasteurisation temperature, so that values were apparently higher after pasteurisation. Values for riboflavin content increased with increasing amounts of milk in the test medium, so that average figures could not be given. Riboflavin content of milk was considerably less in winter with the cows indoors than in summer with the cows on pasture.

There was a slow decrease in nicotinic acid content during winter to a minimum of 70 µg. per 100 ml. in March. The value rose to a maximum of 101 in May and then fell to the normal of from 80 to 85, the yearly average being 82 for raw milk and 82.5 for pasteurised.

Biotin content varied greatly between cows and between samples from individual cows; a slow decrease occurred from autumn to spring. The yearly average was 20.4 µg. per litre.

Pantothenic acid content also varied considerably, with particularly low values in August and September. The yearly average was 2.9 µg. per ml. for raw and 2.95 for pasteurised milk.

There appeared to be no loss of any of the vitamins during sterilisation.

The riboflavin and pantothenic acid values for buttermilk did not differ greatly from those for raw milk, but those for nicotinic acid and biotin were considerably less, suggesting decomposition by the bacteria used in preparing buttermilk.

2999

FRENCH, R. B., ABBOTT, O. D. and TOWNSEND, R. O. **Levels of thiamine, riboflavin and niacin in Florida-produced foods.** *Florida Agric. Exp. Stat. Bull.* No. 482, August 1951, pp. 19.

Vitamin B₁, riboflavin and nicotinic acid were estimated microbiologically in the edible portion of 25 fruits, 4 vegetables, 5 nuts, 10 wild greens, and other products of Florida. Comprehensive tables of the results are given including varietal differences, and one relating average servings to recommended daily requirements of vitamins. Suggestions are made to simplify the technique of the methods used.

Fruits were low in all 3 vitamins; the highest values for nicotinic acid were found in avocado pear, banana, canistel, guava, tamarind and passion fruit. Passion fruit contained a moderate amount of riboflavin.

Green leafy vegetables were good sources, especially collards. Of plants grown as feed for stock, clovers were best. Swede turnip, carrot, and potato and sweet potato had moderate values for vitamin B₁ and nicotinic acid. Seed crops had better balanced contents of vitamins; green lima beans and English peas were particularly rich in vitamin B₁ and nicotinic acid, and summer squash in nicotinic acid.

Coconut had low values; peanuts were high in vitamin B₁, pecan nuts in riboflavin and both in nicotinic acid. Water oak acorns for pigs were high in nicotinic acid and carotene, fair in riboflavin. Peanuts, on roasting, lost a considerable amount of vitamin B₁ but not of the other vitamins.

Among other foods, pork was high in vitamin B₁ and nicotinic acid, and a diet of maize gave a higher content of vitamin B₁ than one in which 40 per cent. of the maize was replaced by cane or citrus molasses.

Ten species of fish were examined and found high in nicotinic acid. Eggs and milk were good sources of riboflavin. Short-time pasteurisation or homogenisation of milk caused no loss.

BANERJEE, S., ROHATGI, K. and LAHIRI, S. **Pantothenic acid, folic acid, biotin and niacin contents of germinated pulses.** *Food Res.*, 1954, 19, 134-137. [Dept. Physiol., Presidency Coll., Calcutta.]

Seeds of *Lathyrus sativus*, *Phaseolus mungo*, *Pisum sativum*, *Cajanus indicus*, *Ph. radiatus*, *Cicer arietinum* and *Lens esculenta* were germinated out of direct sunlight for from 2 to 4 days at 30° C. Before and after germination pantothenic, nicotinic and folic acids and biotin were estimated microbiologically.

The nicotinic acid content of all the pulses and the biotin content of all but *L. sativus* increased

during germination. Pantothenic acid increased in *L. sativus*, *Ph. mungo*, *C. indicus* and *C. arietinum* and remained unchanged in the others. Folic acid values decreased in all.

Tables of values are given. Germinated pulses are recommended as food.—V. R. Jackson.

3001

HALL, A. P., WHEELER, P., THIELEN, A. and MORGAN, A. F. **A new B vitamin study of walnuts.** *Food Res.*, 1953, **18**, 574–577. [Agric. Exp. Stat., Univ. California, Berkeley.]

Vitamin B₁ was estimated by the thiochrome method, and riboflavin, vitamin B₆ and nicotinic, pantothenic and folic acids microbiologically, in the 1950 and 1951 crops of walnuts (*Juglans regia*) grown in California. Three varieties were studied, Payne, Placentia and Franquette, and values are compared with those obtained in earlier work (Abst. 397, Vol. 19).

Values in mg. per 100 g. were for vitamin B₁ 0.24 to 0.28, riboflavin 0.12 to 0.17, nicotinic acid 0.86 to 1.23, pantothenic acid 0.49 to 0.95, folic acid 0.13 to 0.23 and vitamin B₆ 0.87 to 1.05. Nicotinic acid values were 40 to 60 per cent. higher in the second study with an improved method of extraction; those for vitamin B₁ and riboflavin agreed. Rat growth methods of estimation gave for pantothenic acid a value of 1.09, for vitamin B₆ one similar to that obtained microbiologically. Payne and Placentia varieties had a significantly higher content of all 6 vitamins than the Franquette variety. No difference was found between values for the 2 crops except that pantothenic acid values were higher in 1951 than in 1950.—V. R. Jackson.

FANG, S. C., BULLIS, D. E. and BUTTS, J. S. **Investigation of Barcelona and Du Chilly filbert nuts. 3. Amino acid and B vitamin contents of oil-free filbert nut meals.** *Food Res.*, 1953, **18**, 555–559. [Dept. Agric. Chem., Agric. Exp. Stat., Oregon State Coll.]

For previous paper see Abst. 1559, Vol. 20.

Barcelona and Du Chilly filbert nuts (*Corylus avellana*) of the 1946–48 crops were extracted with light petroleum and ground to a fine powder. Amino-acids and 6 B vitamins were estimated microbiologically. The meals were examined as sources of protein for young rats given the diet of Bubl and Butts (Abst. 4601, Vol. 18) except that 16.5 per cent. of intact protein was used and cellulose was omitted from diets containing nut meal.

Of the 17 amino-acids examined, the percentage of valine, proline, serine, aspartic acid and lysine was slightly higher, of methionine the same, and of cystine, threonine and tryptophan lower, in the filbert nut meals than in filbert nut globulins (Abst. 1559, Vol. 20). Compared with casein, the meals were high in arginine and serine, and low in lysine, proline, tyrosine and methionine. It is considered that the balance of amino-acids was good for a plant protein. The growth of young rats showed that the protein was good but inferior to casein. Supplements of tryptophan, cystine and lysine, especially of the last, caused improvement.

The meals were rich in B vitamins, especially biotin. A table is given comparing the values with those for other natural protein foods.

VITAMIN B₁ (ANEURIN, THIAMINE)

3003

BALKRISHNAN, S. and RAJAGOPALAN, R. **Intestinal thiamine synthesis as influenced by different fats.** *Indian Med. Gaz.*, 1953, **88**, 575–576. [Dept. Biochem., Indian Inst. Sci., Bangalore 3.]

Three comparable groups each of 6 rats were maintained for 4 weeks on a diet of vitamin-free casein, lactose, salt mixture and butterfat or coconut oil or groundnut oil. Each rat received in addition supplements of vitamins A and D and of the vitamin B complex. The rats receiving butterfat grew better, excreted more vitamin B₁ in the urine and faeces, had a higher content of vitamin B₁ in the liver, and in the faeces a higher bacterial count, both total and coliform, than the rats on coconut or groundnut oil.

N.A. and R., July 1954

da parte dei colombi. [Ultimate possibility of vitamin B₁ synthesis by pigeons.] *Boll. Soc. ital. Biol. sper.*, 1953, **29**, 1086-1087. [Ist. Fisiol., Univ. Palermo.]

Of 32 adult pigeons fed on polished rice, 8 were given no supplement, 6 were given a daily oral dose of 100 μ g. 2-methyl-4-amino-5-methylpyrimidine hydrochloride together with 100 μ g. 4-methyl-5- β -hydroxyethylthiazole, 6 were given the same by intramuscular injection, 6 were given orally daily 500 μ g. 2-methyl-4-amino-5-amino-methylpyrimidine hydrochloride together with 500 μ g. 4-methyl-5- β -hydroxyethylthiazole, and 6 received the same by intramuscular injection. The supplements had no effect on the course of vitamin B₁ depletion.

In contrast with previous findings with rabbit kidney and liver (see preceding Abst.) there was no synthesis of vitamin B₁ *in vitro* from 2-methyl-4-amino-5-chloromethylpyrimidine and 4-methyl-5- β -hydroxyethylthiazole by homogenates of liver or kidney from normally fed pigeons.—E. M. Hume.

3006

GOETHART, G. The occurrence of free thiamine pyrophosphate in the soluble fraction of rat liver homogenate. *Biochim. biophys. Acta*, 1954, **13**, 138-139. [Lab. Physiol. Chem., Univ. Utrecht.]

A soluble fraction of rat liver was prepared by centrifuging a homogenate in sucrose solution. Free vitamin B₁ pyrophosphate was estimated manometrically in 2 portions of the supernatant fluid at pH 6.2, one of which had been previously boiled at pH 3 to liberate any vitamin B₁ pyrophosphate bound to protein. The results ranged from 1.3 to 1.6 μ g. per ml. soluble fraction without boiling, and from 1.2 to 1.3 after boiling, and suggested that the vitamin B₁ pyrophosphate occurred in the free state in the cell fluid.

The soluble fraction was passed for 1 hr. at 4° C. through a protein-tight collodion filter, and pyrophosphate was estimated in the original fraction and in the ultrafiltrate. A larger proportion was found in the ultrafiltrate than in the unfiltered fraction, again indicating that a large proportion of vitamin B₁ pyrophosphate occurred free in the cytoplasmic fluid of the cells.

It is presumed that though this form is liable to decomposition by phosphatase in the living cell, it is resynthesised at an equal rate by re-phosphorylation of the vitamin B₁ formed.—V. R. Jackson.

SILIPRANDI, D. and LAVIANO, F. The level of blood cocarboxylase after administration of thiamine and its phosphoric esters. *Experientia*, 1953, **9**, 420-421. [Inst. Biol. Chem., Univ. Rome.] French summary.

Vol. 24, No. 3

Six dogs receiving a standard diet were given at weekly intervals intravenous injections per kg. bodyweight of 3 mg. vitamin B₁, 4 mg. monophosphothiamine, 5 mg. diphosphothiamine and, finally, 6 mg. triphosphothiamine. Blood carboxylase, estimated by the method of Westenbrink (Title 330, Vol. 20) at intervals during the 24 hr. after each injection, was greatly increased after administration of vitamin B₁ or monophosphothiamine, the maximum value being reached after 2 hr. There was a sharp increase immediately after di- or triphosphothiamine was given, but values were not as high between the first and third hours as after vitamin B₁ or monophosphothiamine. It was evident that the phosphoric esters were more effective than vitamin B₁ in maintaining a high concentration of cocarboxylase in the blood for 24 hr. It was shown that triphosphothiamine was not split at once into monophosphothiamine and pyrophosphate *in vivo* as it is *in vitro* (Viscontin *et al.*, *Helv. chim. Acta*, 1949, **32**, 1478).

ROSSI FANELLI, A., SILIPRANDI, N., FASELLA, P., SILIPRANDI, D. and SALVETTI, F. L. Ricerche sulla fosforilazione *in vivo* della tiamina. [Phosphorylation of vitamin B₁ *in vivo*.] *Boll. Soc. ital. Biol. sper.*, 1953, **29**, 961-962. [Ist. Chim. Biol., Univ. Rome.]

Adenosinetriphosphate containing ³²P was prepared from the muscles of a rabbit which had previously had radio-active Na phosphate injected intravenously. Rats weighing 200 g. were injected intravenously with, per kg. bodyweight, the radio-active adenosinetriphosphate 30 mg. and vitamin B₁ 20 mg. The rats were killed 30 or 60 min. later and, in extracts of the liver, the mono-, di- and triphosphates of vitamin B₁ were isolated chromatographically. Localisation of ³²P showed it to be present in the di- and tri- but not in the monophosphate.—E. M. Hume.

BARTLEY, W. Metabolism of thiamine phosphates in washed suspensions of kidney particles. *Biochem. J.*, 1954, **56**, 379-387. [Dept. Biochem., Med. Res. Counc. Unit Res. Cell Metabol., Univ. Sheffield.]

Paper chromatography of vitamin B₁, its derivatives and other N compounds is described in which the solvent system was *p*-toluene sulphonic

acid, *tert*-pentanol and water, and the spraying agent potassium bismuth iodide. Particulate suspensions of sheep's kidney were prepared as described previously (*Biochem. J.*, 1953, **53**, 305) and the ratio of oxygen uptake to consumption of pyruvate during incubation was estimated after intervals in the presence of vitamin B₁ or its derivatives.

Vitamin B₁, its monophosphate, cocarboxylase, oxythiamine or its diphosphate, did not alter respiration or ratio of oxygen uptake to pyruvate consumption, but the addition of 0.005 *M* vitamin B₁ triphosphate inhibited respiration by 40 per cent. without altering the ratio. Cocarboxylase was converted during incubation into vitamin B₁ monophosphate; apart from the monophosphate and the three P-containing compounds present in the original incubation mixture, phosphopyruvate and an unknown P compound were found. Labelled P in the medium showed that cocarboxylase slowly incorporated small amounts of inorganic orthophosphate, and there was no relationship between the amounts of cocarboxylase broken down and of pyruvate oxidised, showing that cocarboxylase is not a phosphate carrier in this reaction.

The amount of cocarboxylase broken down in the presence of pyruvate or α -oxoglutarate was less than in their absence or than in the presence of succinate. More labelled P was incorporated into the monophosphate formed when the substrate was oxidisable. No monophosphate was formed during incubation of vitamin B₁ with kidney particles in the presence of pyruvate or fumarate, nor was cocarboxylase formed from vitamin B₁ monophosphate, indicating the absence of a phosphorylating enzyme. The absence of enzyme was confirmed in conditions where monophosphate was stable and not converted to free vitamin. Any radio-activity found in monophosphate is ascribed to the agency of "lipothiamide", a reactive form of vitamin B₁, and a scheme of reactions is postulated to explain the results obtained.

3011

KIESSLING, K. H. **Thiamine triphosphate in bakers' yeast.** *Nature*, 1953, **172**, 1187-1188. [Inst. Zoophysiol., Univ. Upsala.]

A yeast extract rich in vitamin B₁ phosphates was prepared by adding vitamin B₁ to the yeast culture in the presence of glucose (Abst. 3240, Vol. 12). After a crude purification, the phosphates and remaining vitamin B₁ were chromatographed by the method of Kiessling and Lindahl (Abst. 1762, Vol. 24) and the results were compared with those for a mixture of vitamin B₁ and synthetic phosphates. Spraying with alkaline K ferricyanide in alcoholic solution gave spots which fluoresced in ultraviolet light. The mixtures behaved in the same way and gave evidence

of the great ability of baker's yeast to synthesise di- and triphosphates of vitamin B₁.

MATRACIA, S., BARRESI, M. and PASQUALINO, A. Azione della cocarbossilasi e della tiamina sui glucidi nella fatica sperimentale. [Action of cocarboxylase and of vitamin B₁ on sugars in experimental fatigue.] *Boll. Soc. ital. Biol. sper.*, 1953, **29**, 459-460. [Ist. Patol., Univ. Palermo.]

Groups of 6 guineapigs were given an intramuscular injection of 25 mg. cocarboxylase or 23 mg. vitamin B₁ half an hour before being made to take exercise to the point of exhaustion. They were killed immediately afterwards. For animals given no addition and for those given vitamin B₁ or cocarboxylase the respective mean values were for blood sugar in mg. per cent., before exercise 116, 115, 116, after exercise 64, 68, 62, and for glycogen, in mg. per cent., in the liver 0.13, 0.16, 0.17, and in the muscle 0.68, 0.77, 0.78.

When exercise was only for 5 min. there was a slight rise in blood sugar, and the respective values for liver glycogen were 1.86, 2.06 and 2.20, and for muscle glycogen 1.08, 1.35 and 1.37. For non-fatigued [presumably untreated] animals, the values for liver and muscle glycogen were, respectively, 2.27 and 0.68. Treatment with vitamin B₁ or cocarboxylase thus did not affect the blood values, but after mild exercise did reduce or prevent the fall in liver glycogen and increased the rise in muscle glycogen.—E. M. Hume.

WRIGHT, R. C. and SCOTT, E. M. **Pyruvate and α -ketoglutarate metabolism in thiamine deficiency.** *J. Biol. Chem.*, 1954, **206**, 725-733. [Arctic Health Res. Centre, U.S. Pub. Health Serv., Anchorage, Alaska.]

Rats were given diets containing, per cent., casein 24, fat 20 and sucrose 52, or casein 34 and fat 60.5, with mineral and vitamin supplements, except that vitamin B₁ was given only to some of the animals. The oxygen uptake of homogenates of liver, kidney, heart and brain was measured in a Warburg apparatus with different substrates. In general, vitamin B₁ deficiency reduced oxygen uptake, the decrease being greatest with pyruvate as substrate. There was little decrease in oxygen uptake of deficient tissues with α -ketoglutarate as substrate. When vitamin B₁ pyrophosphate was added to the homogenates from deficient animals, the oxygen uptake rose steeply with pyruvate but there was little effect with α -ketoglutarate. The homogenates from animals on the high-fat diet did not differ in enzymic properties from those from animals on the normal diet, but the animals having a high fat intake were larger and lived

N.A. and R., July 1954

longer without a supplement of vitamin B₁. The results support the view that, with a high-fat diet, lack of vitamin B₁ is less serious because the normal oxidation of fat, unlike that of carbohydrate, bypasses the oxidation of pyruvate.—A. M. Copping.

HACKEL, D. B., GOODALE, W. T. and KLEINERMAN, J. **Effects of thiamin deficiency on myocardial metabolism in intact dogs.** *Amer. Heart J.*, 1953, **46**, 883–894. [Dept. Pathol., Sch. Med., W. Reserve Univ., Cleveland, Ohio.]

For the method see Title 2798, Vol. 24.

The myocardial metabolism of dogs deprived of vitamin B₁ was compared with that of normal and of starved dogs (Abst. 3286, Vol. 24).

In 7 dogs with acute vitamin B₁ deficiency the mean arterial lactate level was high. The arterio-venous difference was less than that of normal and similar to that of starved dogs. Less than the normal amount of lactate was used per min. by the left ventricle. The arterial pyruvate level also was high, but the mean arterio-venous difference and total pyruvate utilisation were normal. Glucose utilisation was similar to that of starved dogs.

In normal and starved dogs oxygen uptake was independent of the rate of coronary blood flow, but in vitamin B₁ deficiency the extraction was limited at higher rates of flow.—V. R. Jackson.

ORABONA, M. L. Azione comparativa della aneurina e della cocarbossilasi nel beri-beri complicato da squilibri vitaminici. [**Comparative effects of vitamin B₁ and cocarboxylase in beriberi complicated by vitamin imbalance.**] *Internat. Ztschr. Vitaminforsch.*, 1954, **25**, 170–175. [Ist. Clin. Med., Univ. Bari.] French, English and German summaries.

Of 38 pigeons maintained on a diet without vitamin B₁, 14 were given daily 10 mg. folic acid, 15 received daily 15 mg. nicotinic acid, and 9 had no supplement. When signs of vitamin B₁ deficiency were evident, those without supplements were given an injection of 25 mg. vitamin B₁, and all except 1 recovered. In the groups given nicotinic acid or folic acid, some were given 25 mg. vitamin B₁, and all died except one having nicotinic acid; the remainder were given 25 mg. cocarboxylase, and all recovered except 1 which died and 1 which remained paralysed. It is concluded that excess of nicotinic acid or folic acid interfered with the phosphorylation of vitamin B₁.

E. M. Hume.

3016

DESSI, P., LABÒ, G. and GIANNI, A. M. Sulle interazioni dell'aneurina con la vitamina B₁₂. [**Interaction of vitamin B₁ with vitamin B₁₂.**]

Vol. 24, No. 3

Acta vitaminol., 1953, **7**, 253–256. [Ist. Clin. Med. Gen., Univ. Bologna.] French, English, German and Spanish summaries.

Of 20 male rats weighing about 120 g., given a diet deficient in vitamin B₁, 10 received every 5 days a subcutaneous injection of 500 µg. vitamin B₁₂ per kg. bodyweight; 12 injections in all were given. After 62 days the rats given vitamin B₁₂ were losing weight with signs of polyneuritis, while those without vitamin B₁₂ were still growing. Seven out of 10 recovered when vitamin B₁ was given. The same result was obtained with 2 litters of 9 and 10 rats, divided in half and treated from weaning in the same way as described above, vitamin B₁₂ being given orally at the rate of about 75 µg. per kg. bodyweight daily. Given intraperitoneally vitamin B₁₂ had no such deleterious effect. When weanling rats were used, born of parents maintained for 53 days on a diet deficient in vitamin B₁, those given and not given vitamin B₁₂ grew equally badly, but those not given vitamin B₁₂ survived longer.—E. M. Hume.

RODGER, F. C. **Degenerative changes in the rat visual pathway when thiamin and riboflavin deficiencies are combined.** *Brit. J. Ophthalmol.*, 1954, **38**, 144–155. [Dept. Physiol., Med. Sch., Univ. Durham.]

The description of diet and technique given here should be taken as applicable and supplementary to the account of experiments published earlier (Abst. 2904, Vol. 23). The diet was of casein 15, salt mixture 4, glucose 70, synthetic water-soluble vitamins in solution (500 or 10 µg. per ml.) 10, and synthetic vitamin E in cod liver oil 6 to 10 drops. The "chronic" vitamin B₁ deficiency in the series described here was subacute, but that referred to in Abst. 2904, Vol. 23 was produced by careful variation of the supplementary vitamin B₁ to control anorexia. Riboflavin, 0.3 mg., was given or withdrawn at will.

The series included acute deficiency of vitamin B₁ and riboflavin produced by withdrawal of riboflavin, change from the high to the low vitamin B₁ solution and addition of Pyriethiamin (Merck), duration 19 days; chronic riboflavin deficiency, duration 220 days; chronic vitamin B₁ deficiency with high-carbohydrate diet, duration 85 days; and chronic deficiency of both, duration 200 days. The criteria of deficiency were the usual ones. There were pair-fed controls that remained normal.

In acute deficiency of vitamin B₁ and riboflavin there was anorexia, convulsions and degeneration of parts of the sciatic nerves, but no change in the retina or optic nerve, nor was there any in chronic (220-day) deficiency of riboflavin. In subacute deficiency (85 days) of vitamin B₁ there were

changes in the optic nerve like those already described as due to chronic deficiency (Abst. 2904, Vol. 23), but less severe; in the deficiency of both vitamins the rats lived longer and showed similar more advanced changes. There was no damage to the retina, and it is doubtful whether the riboflavin deficiency was sufficiently prolonged to produce any possible characteristic change.

It is argued from these results that the treatment of amblyopia in prisoners of war should have been with vitamin B₁ and a well balanced diet, not with excess of vitamins.—V. R. Jackson.

KEMÉNY, T., KERTAI, P. and WEISZ, P. Wirkung des Aneurins auf das Hypophysen-Nebennierensystem. [Effect of vitamin B₁ on the anterior pituitary and adrenal system.] *Acta physiol. hung.*, 1954, **5**, 131-137. [Pathophysiol. Inst., Med. Univ., Budapest.] Russian summary.

Adrenocorticotrophic hormone activity in adult rats was assessed by measuring the change in the ascorbic acid content of the adrenal glands after unilateral adrenalectomy and other treatments including section of the spinal cord between the first and second dorsal vertebrae. Ascorbic acid was estimated by a modification of the dinitrophenylhydrazine method. After section of the spinal cord, subcutaneous injection of adrenaline or histamine greatly reduced the ascorbic acid content of the adrenal glands, which was prevented if 2 mg. vitamin B₁ per 100 g. bodyweight were given subcutaneously. Vitamin B₁ injected after removal of one adrenal gland inhibited the fall in ascorbic acid in the other. Eosinopenia induced by adrenaline in intact rats was inhibited by vitamin B₁, but the inhibition did not occur if adrenocorticotrophic hormone was administered. Injection of 1.5 mg. vitamin B₁ per 100 g. bodyweight was only partly effective against the adrenal changes and less was ineffective; the dose of 2 mg. maintained its effect for at least 12 hr. after injection. The results are discussed with reference to assessment of adrenocorticotrophic hormone potency.—A. M. Copping.

3019

GUGGENHEIM, K. Effect of posterior pituitary hormone on water metabolism in thiamine deficiency. *Metabolism*, 1954, **3**, 44-48. [Lab. Nutrit., Hebrew Univ.-Hadassah Med. Sch., Jerusalem.]

In adult male rats, after a water load of 8 per cent. of the bodyweight, the diuretic effect was delayed in vitamin-B₁-deficient animals but not in animals on the same deficient diet supplemented with 0.2 mg. vitamin B₁ per 100 g.; the diet was given to appetite or in amounts equal to those

eaten by the deprived rats. When 50 milli-units of Pitressin in 0.1 ml. saline were given intravenously or intrahepatically 30 min. after the water, excretion of urine was depressed to a greater extent in the deficient rats than in the rats of either non-deprived group. In the non-deprived rats only, the antidiuretic effect of Pitressin was greater when given subcutaneously than when given intrahepatically. The deficient rats excreted more Pitressin in the urine than the non-deprived after the same dose of the hormone. Experiments *in vitro* with extracts of the livers showed that less of the antidiuretic hormone was inactivated by the livers of the deficient rats than of the non-deficient. The addition of vitamin B₁ to the preparations did not restore the capacity to inactivate the hormone. L. Wills.

RINDI, G., FERRARIE, G. and PERRI, V. Correlazione tra piruvato del sangue, aneurina nei tessuti e ipertrofia surrenale nell'avitaminosi B₁ del ratto. [Correlations between blood pyruvic acid, tissue vitamin B₁, and adrenal hypertrophy in vitamin B₁ deficiency in the rat.] *Internat. Ztschr. Vitaminforsch.*, 1954, **25**, 210-224. [Ist. Fisiol., Univ. Pavia.] French, German and English summaries.

Rats weighing from 55 to 60 g. were maintained on a diet complete except for vitamin B₁, and were killed at frequent intervals up to 26 days. The adrenal glands were weighed. Pyruvate was estimated in the blood, and vitamin B₁ by the thiochrome method in the liver, leg muscles and brain. Bodyweight rose slightly and then fell. If the initial mean values are taken as 100, the final mean values were bodyweight 95, weight of adrenal glands 158, blood pyruvate 270, and vitamin B₁ content of liver 5.6, of muscle 21, and of brain 25. Statistical analysis revealed a strong positive correlation between the weight of the adrenal glands and the blood pyruvate value, and a strong negative correlation between the former and the content of vitamin B₁ in the tissues. The increase of pyruvate in the blood was slow at first, and was more closely correlated with the increase in adrenal gland weight than with the decrease of vitamin B₁ in the tissues. There was little correlation between bodyweight and any of the other values.—E. M. Hume.

CACIOPPO, F. Contenuto di cocarbossilasi (APP) nei tessuti di colombe trattati con "orizotossina". [Content of cocarboxylase in the tissues of pigeons treated with oryzatoxin.] *Boll. Soc. ital. Biol. sper.*, 1953, **29**, 479-481. [Ist. Fisiol., Univ. Palermo.]

Of 12 pigeons maintained on a diet of polished rice, 6 received in addition a daily intramuscular

N.A. and R., July 1954

injection of oryzatoxin. When birds receiving oryzatoxin showed signs of polyneuritis they were killed with corresponding birds in the group without oryzatoxin, and cocarboxylase was estimated by the method of Westenbrink (Absts. 241, Vol. 10; 2936, Vol. 11) in the liver and pectoral muscle. For birds with and without oryzatoxin the respective mean values in $\mu\text{g. per g. tissue}$ were for the liver 5.7 and 8.6, and for the muscle 2.3 and 4.1.

E. M. Hume.

3022

MANNELL, W. A. and ROSSITER, R. J. **Nutritional deficiency and Wallerian degeneration in the rat. 2. Effect of thiamine deficiency on the concentration of nucleic acid and phospholipid in intact and sectioned nerves.** *Brit. J. Nutrition*, 1954, 8, 56-64. [Dept. Biochem., Univ. W. Ontario, London, Canada.]

The methods employed followed those described elsewhere (Abst. 3304, Vol. 24). Rats received for 44 days an adequate basal diet or one deficient in vitamin B₁. In some rats the sciatic nerve was cut and, after 8 days, the concentration of nucleic acid and phospholipin in intact and degenerating nerve was estimated. The values were compared with those for animals of the same age receiving adequate vitamin B₁, called age controls, for younger animals receiving adequate diet but killed when the bodyweight was the same as in deprived rats, called weight controls, and for animals of the same age receiving adequate diet restricted in amount, called weight and age controls.

In the age controls concentrations of nucleic acid and phospholipin in nerve tissue decreased with increasing age and bodyweight, and the previous observation was confirmed that, in the intact sciatic nerve of the rat, the concentration of nucleic acid was characteristic of age but not of bodyweight, and the concentration of phospholipin was characteristic of bodyweight but not of age. In rats deprived of vitamin B₁, the concentration of nucleic acid was less than in the weight controls, but did not differ from that in the age controls; concentrations of phospholipin did not differ from that in the weight controls but were greater than in the age controls.

After section of the sciatic nerve, increase in the concentration of nucleic acids occurred more slowly in rats deprived of vitamin B₁ than in the weight controls, which were younger animals, but at the same rate as in the other 2 sets of controls. The decrease in concentration of phospholipin in nerves from deprived animals took place more slowly than in nerves from any control. The result distinguished the effects of vitamin B₁ deficiency from those of lack of protein or of total calories.

There was no evidence that during degeneration of the sciatic nerve proliferating Schwann cells

provided enzymes which destroyed the myelin sheath, since there was no destruction of myelin or loss of myelin lipids.—V. R. Jackson.

3023

SCHNEUNERT, A. and HAENEL, H. Über die Wirkungen zweier Vitamin-B₁-Analoga nach Dornow und deren Antagonisten im Taubentest. [The effects of two of Dornow's analogues of vitamin B₁ and their antagonists in the pigeon test.] *Hoppe-Seyler's Ztschr.*, 1953, 295, 354-362. [Anst. Vitaminforsch., Potsdam-Rehbrücke.]

Two analogues of vitamin B₁ in which the pyrimidine component was replaced by a pyridine group, and their corresponding antivitamin, in which the thiazole moiety was replaced by a pyridine derivative with corresponding structure, were prepared and tested on pigeons deprived of vitamin B₁. Some vitamin B₁ activity was present in an analogue with 2-amino-6-methylpyridyl-(3)-methyl substituted for the pyrimidine moiety. Introduction of a further methyl group in the 4-position removed the vitamin activity. The antivitamin showed comparable changes in activity and the results were confirmed by microbiological tests.—A. M. Copping.

PUTIGNANO, T. and RAMUNNI, M. Azione favorente dell'idrazide dell'acido isonicotinico e dell'acido p-amino-salicilico sul beri-beri sperimentale. [Action of isonicotinic acid hydrazide and of p-aminosalicylic acid in promoting experimental beriberi.] *Acta vitaminol.*, 1953, 7, 257-259. [Ist. Clin. Med., Univ. Bari.] French, English, German and Spanish summaries.

Of 5 groups of pigeons maintained on a diet of polished rice, 2 groups received 250 mg. p-aminosalicylic acid daily orally or by intramuscular injection, 2 groups received 12 mg. isonicotinic acid hydrazide in the same ways, and the fifth received no addition. Signs of vitamin B₁ deficiency appeared in the 2 groups treated orally more quickly than in the other 3 groups.—E. M. Hume.

FORENBACHER, S. Über die B₁-Avitaminose bei Pferden in Jugoslawien, mit besonderer Berücksichtigung der Rolle des Thiamins in der Pathogenese der Schachtelhalmvergiftung. [Vitamin B₁ deficiency in horses in Yugoslavia, with special reference to the role of vitamin B₁ in the pathogenesis of *Equisetum* poisoning.] *Bull. sci. Yugoslav.*, 1953, 1, 87. [Fac. Med., Univ. Zagreb.]

Typical signs of vitamin B₁ deficiency have been reported recently in horses in Yugoslavia

particularly when fed on acid hay containing from 20 to 50 per cent. of *Equisetum arvense* or *E. palustre*. Similar signs have occurred also where the fodder contained dried bracken. Only 4 per cent. of the cases occurred with meadow hay that contained none of these plants. The latent period before the signs appeared was from 2 to 3 weeks with equisetum hay and from 4 to 6 months with meadow hay. The signs disappeared in 2 or 3 days if vitamin B₁ or dried yeast was given, but the amount needed was greater when equisetum hay had been eaten.—W. Godden.

3026

DEOLALKAR, S. T. and SOHONIE, K. **Thiaminase from fresh-water, brackish-water and salt-water fish.** *Nature*, 1954, **173**, 489-490. [Dept. Biochem., Inst. Sci., Bombay.]

Indian fish of 6 different genera, 2 of each from fresh, brackish and salt water, were ground whole, extracted with water and filtered, and the filtrates were tested for thiaminase activity.

Freshwater fish contained a thiaminase with optimum activity at pH 7. The thiaminases of fish from brackish or salt water had optimum activity at pH 3.6, 5.6 and 7.0. The extracts lost activity after dialysis, but addition of the original extract, boiled, restored activity, which suggested the presence of a coenzyme. Mg and Co salts restored the activity of dialysed extracts of the enzymes with optimum activity at pH 3.6 and 5.6. All the enzymes could be precipitated with ammonium sulphate. They could not be separated by fractional precipitation with acetone, ethanol or dioxane, or by the solvents and adsorbents tried. All were adsorbed on fuller's earth, alumina C_γ and bentonite.—V. R. Jackson.

3027

JACOBSON, K. P. and DEODATA DE AZEVEDO, M. Sur l'activation de la thiaminase. [Activation of thiaminase.] *C.R. Soc. Biol.*, 1953, **147**, 1822-1824. [Inst. Rocha Cabral, Lisbon.]

Vitamin B₁ was incubated with extracts of bracken (*Pteridium aquilinum*) or prawn (*Cyrtomium falcatum*) with or without nicotinamide. After 24 hr. in presence of the 2 extracts and nicotinamide, 50 and 36 per cent. of the vitamin B₁ remained, without nicotinamide 100 and 60 per cent. Corresponding values for the loss after 24 hr. of vitamin B₁ without the enzyme extracts were 55 per cent. with nicotinamide and 44 without; losses after 1 hr. were greater in the absence of nicotinamide.—V. R. Jackson.

3028

ZIZZA, F. Ricerche sulla tiaminasi. 4. Comportamento della piruvemia nei colombi sottoposti a somministrazione di estratti di *Venerupis*

decussata. [Thiaminase. 4. Behaviour of blood pyruvic acid in pigeons given extracts of *Venerupis decussata*.] *Boll. Soc. ital. Biol. sper.*, 1953, **29**, 484-487. [Ist. Fisiol., Univ. Palermo.]

Groups of 6 pigeons fed on maize were given daily by mouth an aqueous extract of the mollusc *Venerupis*, prepared by the method of Cacioppo *et al.* (Absts. 1728, Vol. 21; 1912, Vol. 22), or the same extract heated for 10 min. at 100° C., or the unheated extract with a daily intramuscular injection of 2 mg. vitamin B₁. The birds given the unheated extract died in from 4 to 12 days with great neuromuscular disturbance; those given the heated extract died in from 8 to 14 days with less neuromuscular disturbance. The birds given unheated extract with vitamin B₁ died in from 16 to 32 days with the same signs as those given the heated extract. Pyruvic acid in the blood rose to 3.76 from 1.48 mg. per 100 ml. in the first group, but was not affected in the other two. It is concluded that *Venerupis* contains a heat-stable toxin as well as thiaminase.—E. M. Hume.

3029

KIMURA, R. and LIAO, T. H. **A new thiamine decomposing anaerobic bacterium, *Clostridium thiaminolyticum* Kimura et Liao.** *Proc. Japan Acad.*, 1953, **29**, 132-133. [Microbiol. Inst., Fac. Med., Univ. Kyoto.]

Another micro-organism that decomposes vitamin B₁ is added to the 2 already reported (Kuno, *Proc. Japan Acad.*, 1951, **27**, 362; 1952, **28**, 235). Nine strains of it were isolated from the faeces of 505 patients and healthy subjects from in and around Kyoto City. The organism is described and its cultural characteristics are listed. It is named *Clostridium thiaminolyticum*, Kimura et Liao.—E. M. Hume.

3030

WAIBEL, P. E., CRAVENS, W. W., BIRD, H. R. and BAUMANN, C. A. **Rhythmic responses of chicks to injected thiamine.** *J. Nutrition*, 1954, **52**, 65-73. [Dept. Poultry Husb., Coll. Agric., Univ. Wisconsin, Madison.]

Chicks were maintained in batteries and from 7 days of age were given a diet lacking in vitamin B₁. On the 9th and 10th day each chick received by injection 9 µg. of vitamin B₁, an amount calculated to support half maximum growth. On the 11th day the chicks were separated into uniform groups of 10. Two groups received 1 or 6 µg. vitamin B₁ per g. diet; 6 groups were given subcutaneous injections for 16 days, the total amount of vitamin B₁ injected being the same in all groups. Intervals between injections varied from 12 to 96 hr. Chicks given adequate or suboptimum amounts of the vitamin in the diet showed a growth rhythm

N.A. and R., July 1954

in which weight increase took place mainly during the day, though food was always available and illumination continuous. The rhythm was intensified in birds injected at 8 a.m. with suboptimum amounts of vitamin B₁. In birds injected at 8 p.m. the rhythm was reversed. The relatively larger increases which occurred after a morning injection were attributed to a sudden increase in the intake of food and water superimposed on the normal, fundamental rhythm. The more frequent the injection, the more efficiently was the vitamin utilised. The amount of vitamin B₁ required to be injected per g. weight increase was, in $\mu\text{g.}$, twice daily 1.78 to 1.82, once daily 2.22, every other day 3.53, every 4th day 4.82. For chicks given adequate dietary vitamin B₁ the amount was 2.15 $\mu\text{g.}$ daily.—E. M. Cruickshank.

BUTSCHEK, G., KRAUSE, G. and ROSKOPP, W. Der Vitamin B₁-Gehalt von Hefen, seine Beeinflussung und seine Bestimmung mit der Fermentmethode. [Vitamin B₁ content of

yeasts, its control and its estimation by the enzyme method.] *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1954, **98**, 89-105. [Zellstoff Fabrik Waldhof, Werk Kostheim.]

Values reported in the literature for the vitamin B₁ content of yeasts are tabulated, and the wide variations are discussed with reference to methods of culture and of estimating vitamin B₁. In the present study the vitamin was estimated in a number of commercial yeast preparations by the fermentation method of Schultz *et al.* (Absts. 4727, Vol. 7; 198, Vol. 12). The values in mg. per cent. found for dried brewer's yeasts ranged from 15.6 to 27.8 and for pressed baker's yeasts from 2.3 to 2.8. Yeasts grown under special conditions for food or for medicinal purposes showed some very high values for vitamin B₁, up to 95.5 for a dried, vitamin-rich baker's yeast. Tests were made on fresh dried yeasts and on samples stored for from 4 to 11 months, and no evidence was obtained that vitamin B₁ potency was lost during storage.

NICOTINIC ACID (NIACIN)

3035

HOLMAN, W. I. M. A colorimetric method for the determination of the principal metabolites of nicotinic acid in human urine. *Biochem. J.*, 1954, **56**, 513-520. [Med. Res. Coun. Dept. Exp. Med., Univ. Cambridge.]

From the evidence of several groups of workers it appears that the main metabolites of nicotinic acid excreted in human urine are N-methyl-2-pyridone-5-carbonamide and N-methylnicotin-

amide. For the purpose of assessing the nicotinic acid status of man a method of estimating the two substances was developed in which the carbonamide group was converted to an amino-group by heating with hypobromite, diazotised and coupled to yield an azo dye.

If the proportion of hypobromite was large relative to the amount of pyridone present no colour developed, but when the amount of hypobromite was controlled by removing excess with

phenol before heating, azo colour was developed with N-methyl-2-pyridone-5-carbonamide, N-methyl-2-pyridone-3-carbonamide, N-methylnicotinamide and nicotinamide; N-(1-naphthyl-) ethylenediamine dihydrochloride was the coupling agent. The 4 substances gave purple, blue, orange and orange dyes, respectively. The best results were obtained when the dyes were protected from light; slightly more alkaline hypobromite was needed for nicotinamide and its N-methyl derivative. Details are given of methods for estimating from 1 to 50 $\mu\text{g.}$ of the compounds; colours were estimated photo-electrically.

Interfering substances had to be removed from urine; Lloyd's reagent was used for N-methyl-2-pyridone-5-carbonamide and Decalso for N-methylnicotinamide. Details of the methods are given.

Urinary excretion of the two main metabolites was estimated for 3 subjects before and after 600 mg. quinolinic acid, given orally or intravenously. The results showed that only a small amount of the quinolinic acid was converted to nicotinic acid before excretion.—V. R. Jackson.

ALCANTARA E., G. Obtención del ácido nicotínico y nicotinamida a partir de la nicotina del tabaco peruano. [Preparation of nicotinic acid and nicotinamide from the nicotine of Peruvian tobacco.] *An. Fac. Farm. Bioquím., Lima*, 1952, **3**, 449–457. [Lab. Quím. Orgán., Univ. Lima.]

Methods are described for transforming nicotine extracted from tobacco leaves into nicotinic acid and nicotinamide.—A. M. Copping.

3037

STOKELY, P. S. The synthesis of nicotinic acid by *Chilomonas paramecium*. *Exp. Cell. Res.*, 1953, **5**, 320–324. [Biol. Dept., Univ. Notre Dame, Ind.]

The synthesis of nicotinic acid by bacterium-free cells of *Chilomonas* was measured microbiologically with *Lactobacillus arabinosus*. Extraction with takadiastase alone or with papain, with hot HCl or hot water gave closely comparable results but digestion with papain alone gave very low results. The average amount of nicotinic acid obtained was 0.129 $\mu\text{g.}$ per mg. dry weight; it was present in the cells and not in the culture fluid, and manometric measurements of cozymase activity suggested that it was present in the form of diphosphopyridine nucleotide.—A. M. Copping.

3038

VILLA, L. and DIOGUARDI, N. Action of niacinamide on the O_2 consumption by homogenates of rat liver. *Experientia*, 1953, **9**, 469. [Inst. Clin. Gen. Med., Univ. Milan.] French summary.

Homogenates were prepared from livers of rats that had received a mixed natural diet. Nicotinamide was added to the homogenates in a first series after they had stood for 10 min. at 30° C. or in a second series when freshly prepared at 0° C. Oxygen uptake was estimated manometrically. In the first series oxygen uptake was irregular and was not affected by the presence of nicotinamide within the first 240 min. after its addition. In the second series presence of nicotinamide caused a great increase in oxygen consumption. The respiratory rate was not affected by addition of 2:4-dinitrophenol and aureomycin, but respiration was inhibited by α -tocopherol and destroyed by KCN. Respiratory activity of homogenates in presence of nicotinamide was destroyed in 40 min. at 50° C.—V. R. Jackson.

3039

EL RIDI, M. S., ABDEL KADER, M. M., HABIB, A. and ABDEL AZIZ, A. Role of tubercle bacilli in raising the nicotinic acid level in the blood. *J. Egypt. Med. Assoc.*, 1953, **36**, 435–444. [Biochem. Dept., Kasr El Aini Fac. Med., Univ. Cairo.]

Of 30 guineapigs maintained on a diet of clover, 15 were given an intramuscular injection of 2 mg. of a culture of *Mycobacterium tuberculosis*, human type. Animals in both groups were killed after 3, 4 and 6 weeks. For the non-infected and infected animals, respectively, the mean values were for haematocrit 41.6 and 35.3, for blood nicotinic acid 393 and 1405 $\mu\text{g.}$ per 100 ml., and for total pyridine nucleotides in the blood 44.4 and 78.7 $\mu\text{g.}$ per ml.—E. M. Hume.

3040

CHERKES, G. A. Metilirovanie nikotinovoi kisloty v usloviyakh gipotireoza. [Methylation of nicotinic acid in hypothyroid states.] *Vop. Pitan.*, 1954, **13**, 12–15. [Lab. Exp. Patol., Inst. Pitan., Akad. Med. Nauk. SSSR, Moscow.]

The urinary excretion of N¹-methylnicotinamide in response to nicotinamide (20 mg.) was estimated in 7 rats before and after administration of sufficient thiouracil to cause hypothyroidism (20 mg. daily for 20 days). The amount excreted after the second test dose was in every case smaller than that after the first. It is deduced that thyroid hormone exerts an influence on that phase of nicotinic acid metabolism which involves methylation.—D. W. Taylor.

3041

QUAGLIARIELLO, G. and PORCELLATI, G. Sulla presenza in un estratto di rene di un enzima amidante l'acido nicotinico. [Presence in a kidney extract of an enzyme transforming

nicotinic acid to amide.] Su di alcune proprietà della nicotinamidasi del rene di maiale. **[Some properties of the nicotinamidase from pig's kidney.]** *Boll. Soc. ital. Biol. sper.*, 1953, **29**, 475-477; 477-479. [Ist. Chim. Biol., Univ. Naples.]

A powdered preparation from an acetone extract of pig's kidney was ineffective in forming nicotinamide from phosphate and ammonium nicotinate. When, however, the Na salt of adenosinetriphosphate was added, considerable amounts of nicotinamide were formed. When the system contained as well Na succinate, succinic dehydrogenase and cytochrome *c*, the amount of nicotinamide was still further increased, although without adenosinetriphosphate the succinic oxidase system alone was ineffective.

In the foregoing experiment synthesis was almost complete in 3 hr. The optimum pH was from 7.0 to 7.2. There did not appear to be any consumption of oxygen during the synthesis. The enzyme was inactivated by dialysis against water, but activity was restored by mixing the two fractions or adding Mg^{++} to the internal one.

E. M. Hume.

3042

CEDRANGOLO, F., DELLA PIETRA, G. and QUAGLIARIELLO, E. Interrelazione triptofano-acido nicotinicco.1.] **[Interrelations of tryptophan and nicotinic acid. 1.]**

CEDRANGOLO, F., QUAGLIARIELLO, E. and DELLA PIETRA, G. 2. *Bull. Soc. ital. Biol. sper.*, 1953, **29**, 481-483; 483-484. [Ist. Chim., Fac. Med., Univ. Naples.]

1. Eggs of Leghorn fowls were inoculated on the 7th day of incubation with from 278 to 887 μg . of neutralised quinolinic acid solution or with saline. On the 18th day, nicotinic acid in the egg was estimated microbiologically with *Lactobacillus arabinosus* 17/5. There was no difference in the content of nicotinic acid between the two sets of eggs, and the quinolinic acid injected remained unchanged.

2. Hydroxyanthranilic acid was injected in the same way, and the result was equally negative.

E. M. Hume.

DELLA PIETRA, G. and QUAGLIARIELLO, E. Sul dosaggio microbiologico dell'acido chinolinico nell'uovo di pollo. **[Microbiological estimation of quinolinic acid in the hen's egg.]**

QUAGLIARIELLO, E. and DELLA PIETRA, G. Variazioni del tasso di acido chinolinico nell'uovo di pollo nel corso dello sviluppo embrionale. **[Changes in the concentration of quinolinic acid in the hen's egg during development of the embryo.]** *Boll. Soc. ital. Biol. sper.*, 1953, **29** 516-518; 518-520. [Ist. Chim., Fac. Med., Univ. Naples.]

Vol. 24, No. 3

The results recorded in the preceeding Abst. are put forward again and discussed.

In hen's eggs nicotinic acid was estimated with *Lactobacillus arabinosus* 17/5 before and after decarboxylation of quinolinic acid by acid autoclaving, the increase in amount of nicotinic acid being taken to represent quinolinic acid. The most satisfactory conditions for autoclaving were at 121° C. for 2 hr. with 2 ml. glacial acetic acid per g. homogenised egg. The mean of the values obtained by the different slight variations of the autoclaving technique was, in μg . quinolinic acid per g. egg, before incubation 0.25 and after 18 days' incubation 2.73.—E. M. Hume.

3044

BUTENANDT, A., SCHULZ, G. and HANSER, G. Über 5-Oxy-kynurenin, seine Synthese und physiologische Bedeutung. **[5-Hydroxykynurenine, its synthesis and physiological significance.]** *Hoppe-Seyler's Ztschr.*, 1953, **295**, 404-410. [Max-Planck Inst. Biochem., Univ. Tübingen.]

Synthesis is described of *dl*-5-hydroxykynurenine on Sørensen's principle for amino-acid preparation (*Hoppe-Seyler's Ztschr.*, 1905, **44**, 448). The synthetic material was inactive in eye-pigment tests with *Drosophila* and *Ephesia*, and could not replace nicotinamide for growth of *Neurospora crassa*. Kynureninase split the substance into alanine and 5-hydroxyanthranilic acid. The results suggested that 5-hydroxykynurenine is not a normal intermediary in tryptophan metabolism or in synthesis of the pigment in the eye of *Drosophila* or *Ephesia*.—A. M. Copping.

3045

DONDERO CORTES, V. Valoración de acido nicotínico en tejidos animales. **[Estimation of nicotinic acid in animal tissues.]** *An. Fac. Farm. Bioquim., Lima*, 1952, **3**, 71-77. [Lab. Invest., Univ. Lima.]

Nicotinic acid was extracted after acid hydrolysis from animal tissues and estimated in the extracts by the CNBr method. In cuts of mutton and beef, values ranged from 3 to 8 mg. per cent., the highest values being found in shoulder of mutton. Chicken meat was poorer, containing on the average 1.5 mg. nicotinic acid per cent. Whale-meat averaged 3.7 mg. The values are of the same order as, though a little below, those reported by investigators in other countries.—A. M. Copping.

3046

HINTON, J. J. and SHAW, B. The distribution of nicotinic acid in the rice grain. *Brit. J. Nutrition*, 1954, **8**, 65-71. [Res. Assoc. British Flour Millers, Cereals Res. Stat., St. Albans.]

Two samples of rice, one a short, broad, white

grain of Egyptian origin and one a long, narrow, red-skinned Indian variety, were dissected by hand into their structural parts and nicotinic acid was estimated in them microbiologically (Heathcote *et al.*, Abst. 449, Vol. 22). Removal of lipid had no effect on the results, so was omitted. Results are given in terms of air-dry weight, with 89 per cent. dry matter.

For the Egyptian and Indian varieties, respectively, the percentage of the grain represented by the pericarp and aleurone layer was 5 and 7, outer endosperm 6.1 and 5.9, inner endosperm 85.6 and 84.8, embryo and scutellum 3.3 and 2.3. The division into outer and inner endosperm was somewhat arbitrary. The total content of nicotinic acid in the dissected grains was 4767 and 7081 mg. per 100 g. The percentage of the total vitamin in different parts of the two varieties was 78.5 and 85.5 for pericarp and aleurone, 11.1

and 7.8 for outer endosperm, 6.7 and 4.5 for inner endosperm, and 3.7 and 2.2 for embryo and scutellum. The differences between the red- and white-skinned varieties were not significant.

Comparison with wheat of comparable total nicotinic acid content showed that the gradient of content in the endosperm, declining from the periphery to the centre, was steeper than in wheat, and that the concentration in rice endosperm was about two-thirds of that in wheat.

The concentration in the pericarp was 6 times that in wheat. The distribution of nicotinic acid differed from that of vitamin B₁, of which 50 per cent. was in the scutellum; in modern milling practice the production of milled rice with a satisfactory nicotinic acid content would present a difficult problem, owing to the presence in the pericarp of so high a proportion of the total nicotinic acid in the grain.—V. R. Jackson.

VITAMIN B₆ (PYRIDOXINE, ADERMIN)

3047

FUKUI, S. **Differential determination of vitamin B₆ group.** *Anal. Chem.*, 1953, **25**, 1884-1886. [Dept. Indust. Chem., Fac. Eng., Univ. Kyoto.]

From extracts containing pyridoxine, pyridoxal and pyridoxamine, a cation exchange synthetic resin removed pyridoxamine, and pyridoxal was destroyed by treatment with acetone and NaOH. At each stage the vitamin B₆ activity was estimated with *Saccharomyces carlsbergensis*. Measurement by this method of the vitamin B₆ components in rice bran, yeast, liver and heart gave results similar to those reported by Rabinowitz and Snell, who used specific micro-organisms to estimate the different components (*cf.* Abst. 4335, Vol. 18).

CONDAL BOSCH, L. and COSÍN GARCÍA, R. Estudios sobre carboxilasas. 2. Determinación cuantitativa de codescarboxilasa (piridoxal-fosfato). [Studies of carboxylases. 2. Quantitative estimation of codecarboxylase (pyridoxal phosphate).] *Rev. española Fisiol.*, 1953, **9**, 189-203. [Inst. Español Fisiol., Madrid.] English summary.

A manometric technique was devised for measuring the rate of reaction between the source of codecarboxylase to be tested and an apodecarboxylase derived from an acetone extract of *Streptococcus faecalis* R. No standard was employed but decarboxylase activity was estimated by calculation and expressed in terms of the activity of pyridoxal phosphate. An approximate formula was derived and a correction applied through a curve of rectification. [It is not possible

to abstract the mathematical material, for which the original paper should be consulted.]

A. M. Copping.

3049

TAPPAN, D. V. and ELVEHJEM, C. A. **Observations on the nutrition of rhesus monkeys receiving highly processed rations.** *J. Nutrition*, 1953, **51**, 469-477. [Dept. Biochem., Univ. Wisconsin, Madison.]

The 5-in-1 army combat ration of processed foods was tested on 6 rhesus monkeys. If no supplement was given the monkeys lost interest in their food and showed signs of malnutrition after about 4 months. Addition of ascorbic acid produced temporary improvement, but further addition of pyridoxine and folic acid was necessary to maintain health and weight. Injections of penicillin and aureomycin to control secondary infections in some animals seemed to have a beneficial effect on their nutritional state. The animals were maintained on the ration with vitamin supplements for from 16 to 26 months. The observations are discussed with reference to previous tests of the rations on rats and to man's need for vitamin supplements.—A. M. Copping.

3050

TAPPAN, D. V., LEWIS, U. J., METHFESSEL, A. H. and ELVEHJEM, C. A. **Studies concerning the pyridoxine requirements of rats receiving highly processed rations.** *J. Nutrition*, 1953, **51**, 479-490. [Dept. Biochem., Univ. Wisconsin, Madison.]

Previous studies (Absts. 2241, 2242, Vol. 18) showed that the K type of emergency army ration

N.A. and R., July 1954

was unsatisfactory for the growth of young rats. It was modified and tested with and without additions, with growth of rats during 4 weeks from weaning as criterion. A supplement of vitamin B₆ was found necessary, which could be provided by replacing pork and egg in the ration by beef. The need for extra vitamin B₆ appeared to arise through the processing of the pork and egg constituents. Substitution of Spam, or chicken, pork and beef loaf, or casein, for the pork and egg also gave improved growth. Further addition of vitamin B₆ always increased the growth response.

Tests with the more elaborate 5-in-1 ration showed that it supported good growth in young rats and that vitamin B supplements produced only slight improvement.—A. M. Copping.

3051

KIRCHER, W. Untersuchungen über die Wirksamkeit des Vitamins B₆ (Pyridoxin) bei diphtherischen Lähmungen. [**Effect of vitamin B₆ (pyridoxine) on paralysis due to diphtheria.**] *Internat. Ztschr. Vitaminforsch.*, 1954, **25**, 175-185. [Kinderklin., Univ. Graz.] English and French summaries.

An injection of diphtheria toxoid of known potency was given to 51 guineapigs; 26 of them received no treatment, and 25 were given daily 2 or 5 µg. vitamin B₆ subcutaneously from 2 days after the injection of the toxoid. Moderately severe localised paralysis was produced in all the untreated animals but in only 17 of the treated; the duration and degree of paralysis was less in the treated, and the onset was delayed. In a further experiment a dose of toxoid lethal to untreated animals was used, and vitamin B₆ had some protective value. A clinical trial in 37 patients with severe diphtheria and paralysis suggested that pyridoxine influenced the paralysis favourably.—L. Wills.

3052

GRADOS RODRIGUEZ, R. Acción de la piridoxina sobre la glucemia. [**Effect of pyridoxine on blood sugar.**] *An. Fac. Farm. Bioquim., Lima*, 1952, **3**, 378-388. [Lab. Farmacol. Exp., Univ. Lima.]

Administration of 0.2, 0.4, 0.6 or 0.8 mg. pyridoxine by mouth or of 0.5, 100, 150 or 200 mg. by intraperitoneal injection raised the blood sugar in rabbits. The peak was attained 2 to 4 hr. after the pyridoxine was given and was higher in male than in female animals. The percentage increase in blood sugar was roughly proportional to the size of the dose given.—A. M. Copping.

3053

BEATON, J. R., BEARE, J. L., BEATON, G. H., WHITE, J. M. and MCHENRY, E. W. **The**

Vol. 24, No. 3

basal metabolic rate and the effects of thiouracil administration and of thyroidectomy on control and vitamin B₆-deficient rats. *J. Nutrition*, 1943, **51**, 599-608. [Dept. Pub. Health Nutrit., Univ. Toronto.]

Groups of comparable rats weighing about 100 g. were given a purified diet containing 20 per cent. fat and 20 per cent. casein. All the rats received 100 µg. deoxypyridoxine daily and two groups received pyridoxine, one fed to appetite and the other with its food intake limited to that of the deficient rats. The average basal metabolic rate was found to be affected by inanition but not further by lack of vitamin B₆. When thiouracil was given to rats deprived of vitamin B₆ it appeared to increase the severity of the skin lesions, but did not cause definite changes in body composition or blood metabolites which could be attributed to exacerbation of the deficiency. Inconclusive results were obtained also in thyroidectomised rats.—A. M. Copping.

CALDWELL, E. F. and MCHENRY, E. W. **Effect of the basal diet on urea formation in vitamin B₆ deficiency.** *Arch. Biochem. Biophys.*, 1954, **48**, 50-54. [Dept. Pub. Health Nutrit., Univ. Toronto.]

Young adult rats received a diet with, per cent., casein 20, maize oil 20 and sucrose 54 with salts and vitamins, but lacking vitamin B₆, for 30 days and then were given an initial dose of 2 mg. urea N per g. bodyweight in normal saline followed by 1 mg. per g. after 3, 6, 9, 12 and 15 hr., or corresponding injections of saline. After 17 hr. urea formation by liver slices *in vitro* was estimated. Those with injections of saline formed only just significantly more urea than those with abnormally high blood concentrations of urea.

In another series rats received a diet with 94 per cent. casein. One group had no supplement; the other had the food intake restricted to that of the first group but was given a supplement of 50 µg. vitamin B₆ daily. After 21 days the rats fasted for 21 hr. and urea formation by the liver was estimated. Liver slices from rats deprived of vitamin B₆ formed more urea than slices from rats having the vitamin but restricted food intake, but the difference just failed to be significant. In both groups, the values were lower than when only 20 per cent. casein was given. To determine whether this partial inhibition was due to the high casein content of the diet, 2 groups of rats received a diet containing 74 per cent. casein with either sucrose or maize oil 20, salts 4, agar 2, and all vitamins. After 7 weeks the rats were fasted for 45 hr. and urea formation by the liver was estimated. There were differences between the 2

groups, those with 20 per cent. fat having the higher urea formation and the lower blood urea values, which were the same as were obtained previously with 20 per cent. casein and fat. (Abst. 439, Vol. 24.)—V. R. Jackson.

The method of Metzler and Snell (Abst. 1968, Vol. 22) was employed with alum as catalyst. Transamination occurred between some peptides and pyridoxal.—W. Godden.

3056

HURWITZ, J. **The enzymatic phosphorylation of pyridoxal.** *J. Biol. Chem.*, 1953, **205**, 935-947. [Dept. Biochem., Sch. Med., W. Reserve Univ., Cleveland, Ohio.]

A kinase was obtained from brewer's yeast and purified by a series of reactions described in detail. The purity of the kinase could be measured by its ability to catalyse the reaction pyridoxal \times adenosinetriphosphate \rightarrow pyridoxal pyrophosphate + adenosinediphosphate. The optimum temperature for the reaction was 47°C. and the pH from 6.6 to 7.0. The presence of a divalent metal such as Zn, Co⁺⁺, Mg⁺⁺, Ni⁺⁺ or Fe⁺⁺ appeared to be essential to the reaction. The kinase was specific for adenosinetriphosphate and other phosphates could not replace it as phosphorylating agent. Adenine, adenosine, adenylic acid, adenosinediphosphate, inositol triphosphate, and pyrophosphate inhibited the phosphorylation. The nature of the inhibition was studied but was not completely elucidated. The kinase was specific for the phosphorylation of pyridoxal, and the formation of pyridoxal phosphate from other pyridoxine derivatives was not explained by these experiments.—A. M. Copping.

CHATAGNER, F., TABECHIAN, H. and BERGERET, B. **Répercussion d'une carence en vitamine B₆ sur le métabolisme de l'acide L-cystéine-sulfinique, *in vitro* et *in vivo*, chez le rat. [Repercussions of a deficiency of vitamin B₆ on the metabolism of L-cysteine sulphinic acid, *in vitro* and *in vivo*, in the rat.]** *Biochim. biophys. Acta*, 1954, **13**, 313-318. [Lab. Chim. Biol., Fac. Sci., Paris.] English and German summaries.

Two groups of young rats received an adequate synthetic basal diet, except that one group was deprived of vitamin B₆. Urine was collected for 24 hr., and amino-acids were estimated chromato-

graphically. Homogenates were made from liver and their enzymic activity in desulphinating transamination and in decarboxylation of cysteine sulphinate was estimated.

After 2 months, the non-deprived rats had gained up to 40 g., and the deprived rats had fallen back to their initial weight and were showing signs of deficiency. Chromatography of the urine showed that large quantities of taurine and a considerable amount of hypotaurine were excreted by the non-deprived rats but not by the deprived, whose urine contained a substance which behaved like cystathionine. The addition of 1 per cent. cysteine sulphinic acid to the rats' diet did not affect the findings, although there was a decrease of total urinary N for which no explanation could be given.

There was little difference between the desulphinating transamination activity of liver from deprived and non-deprived rats, and addition of pyridoxal phosphate to the homogenates had no effect.

The livers of non-deprived rats produced 0.9 mg. hypotaurine per g. fresh liver in 4 hr.; livers from deprived rats, did not form hypotaurine. Addition of pyridoxal phosphate with or without Mg, adenosinetriphosphate or cysteine did not affect the results. It is concluded that the absence of taurine from the urine of the deprived rats was caused by suppression of the decarboxylation of cysteine sulphinic acid.—V. R. Jackson.

BUTLER, L. C. and MORGAN, A. F. **Blood eosinophil levels in the young and adult pyridoxine-deficient rat.** *Proc. Soc. Exp. Biol. Med.*, 1954, **85**, 139-142. [Dept. Home Econ., Univ. California, Berkeley.]

Eight weanling male rats which had been with lactating mothers receiving no vitamin B₆ since 15 days old received a vitamin-B₆-free diet of high protein content. Two comparable groups from normal mothers acted as normal and inanition controls and received complete diet to appetite or with the intake restricted so that weights were similar to those of deprived rats. Three groups of 8 adult male stock rats received similar diets, with the addition of deoxypyridoxine to the diet of the deprived group. Eosinophil counts were made in the young rats at weekly intervals for 9 weeks and in the adult rats at irregular intervals after 25 to 46 days.

In the young animals weight rose to 68 per cent. above initial weight in deprived and inanition controls and to 450 per cent. in normal controls. Xanthurenic acid was found in urine after 2 weeks and acrodynia appeared in the third week. The normal controls showed a continuous and sharp increase in number of circulating eosinophils from 27 to 268 per c.mm. in the eighth week, when no

N.A. and R., July 1954

further rise occurred. In deprived and inanition controls there were gradual and similar increases which did not reach normal levels.

Deprived adult animals and their inanition controls lost 29 per cent. of their weight while normal rats gained 3.5 per cent. Eosinophil levels showed no significant variation in normal rats; in the two other groups there was a gradual fall to a significantly lower level at 33 days, and the level remained low until the end of the test. It is concluded that inanition alone was responsible for the chronic endogenous eosinopenia.—V. R. Jackson.

DIETRICH, L. S. and SHAPIRO, D. M. **Antagonist studies: comparison of desoxypyridoxine and pyridoxine-deficiency therapy on various vitamin B₆ enzymes.** *Proc. Soc. Exp. Biol. Med.*, 1953, **84**, 555-558. [Dept. Biochem., Coll. Phys. Surg., Columbia Univ., New York.]

Two groups of 20 male black mice received a stock diet and 150 mg. deoxypyridoxine per kg. bodyweight, or saline, intraperitoneally daily for 14 days. Two other groups received a synthetic basal diet of high protein content, one complete and the other without vitamin B₆. The animals were killed. Glutamic-aspartic transaminase, dihydroxyphenylalanine (dopa) decarboxylase and cysteine desulphydrase were estimated in the liver.

In mice deprived of vitamin B₆, the activity of all 3 enzymes was significantly reduced, that of cysteine desulphydrase most. Deoxypyridoxine reduced the activity of transaminase greatly and of dopa decarboxylase significantly but less severely; the activity of cysteine desulphydrase was unimpaired.—V. R. Jackson.

BOONE, I. U. and WOODWARD, K. T. **Relationship of pyridoxine and its derivatives to the mechanism of action of isoniazid.** *Proc. Soc. Exp. Biol. Med.*, 1953, **84**, 292-296. [Los Alamos Sci. Lab. (Univ. California), Los Alamos, N. Mex.]

The power of B vitamins to reverse inhibition of growth by isoniazid was investigated with *Lactobacillus plantarum*, *Streptococcus pyogenes*, *Bacterium coli*, *Saccharomyces carlsbergensis*, *Mycobacterium tuberculosis* and *Mycobacterium butyricum*. With *L. plantarum* and *S. carlsbergensis* inhibition by isoniazid was completely reversed by pyridoxine and its derivatives. Pyridoxal and pyridoxamine were from 1000 to 4000 times more effective than pyridoxine itself. With *Bact. coli*, inhibition was only partly reversed by pyridoxine and its derivatives, and with the mycobacteria tested there was no reversal of inhibition. Nicotinic acid, vitamin B₁, pantothenate, p-amino-

benzoic acid and riboflavin had no effect on isoniazid inhibition of *L. plantarum*.

KOTAKE, Y., KOTAKE, Y. (JR.), HISHIKAWA, M., SAKAN, T. and YAMAGUCHI, M. **Studies on xanthurenic acid. 4. Effect of insulin on tryptophan metabolism.** *J. Biochem., Tokyo*, 1953, **40**, 383-386. [Biochem. Dept., Med. Coll., Wakayama.]

In continuation of previous work (Absts. 1973, Vol. 22; 5013, Vol. 23), rats weighing 150 g. were given a single dose of 0.1 g. tryptophan and 0.4 g. Na butyrate, and some were injected with insulin. The urine passed in the ensuing 24 hr. was treated with mercuric acetate, and the precipitate was decomposed with H₂S; the solution was concentrated and subjected to chromatographic analysis on paper. The chromatogram was developed with butanol, acetic acid and water, and the appropriate reagents were applied. In the urine of the rats given insulin, the spot representing xanthurenic acid was much weaker, and the spot representing anthranilic acid was much stronger, than in the urine of the rats not given insulin. The effect had little relation to the size of the dose of insulin. It is concluded that insulin promoted more normal metabolism in rats given Na butyrate with tryptophan.—E. M. Hume.

TENCONI, L. T. **Analisi cromatografica di urine di ratti carenti in axeroftolo o in piridoxina, dopo carico di triptofano. [Chromatographic analysis of the urine of rats deprived of vitamin A or vitamin B₆, after a dose of tryptophan.]** *Boll. Soc. ital. Biol. sper.*, 1953, **29**, 504-505. [Reperto Biol., Lab. Ricerche, Lepetit S.p.A., Milan.]

Rats were maintained on a diet deficient in vitamin A with or without a daily supplement of 125 µg. vitamin A, or on a diet deficient in vitamin B₆ with or without a daily supplement of 100 µg. pyridoxine. After 5 weeks, by which time the rats deprived of vitamin A were beginning to show signs of deficiency, all the rats were given a single oral dose of 500 mg. l-tryptophan per kg. bodyweight. The test was repeated after 10 weeks, when signs of deficiency in both deprived groups were severe. Urine was collected for the 24 hr. after the test and was analysed chromatographically on paper. The changes in the chromatogram caused by administration of tryptophan were not affected by deprivation of vitamin A, but deprivation of vitamin B₆ caused disappearance of anthranilic acid and its conjugates, appearance of 3-hydroxykynurenine and kynurenine, increase of xanthurenic acid and decrease of kynurenine acid. (See Abst. 1796, Vol. 24.)—E. M. Hume.

PIERPOINT, W. S. and HUGHES, D. E. The synthesis of coenzyme A by *Lactobacillus arabinosus* 17-5. *Biochem. J.*, 1954, **56**, 130-135. [Med. Res. Counc. Unit Res. Cell Metabol., Dept. Biochem., Univ. Sheffield.]

Cells of *Lactobacillus arabinosus* 17-5 deficient in co-enzyme A were obtained by culture in a semi-synthetic medium used for estimating pantothenic acid (Barton-Wright, *Practical methods for the microbiological assay of the vitamin B complex and essential amino acids*, Ashe Laboratories, London, 1946). Washed suspensions of the cells in glucose and phosphate buffer were incubated for 1 hr. at 37°C. with no supplement, or with pantothenate with or without other substances. Co-enzyme A was extracted and estimated by the method of Handschumacher *et al.* (Abst. 1784, Vol. 21).

Deficient cells synthesised co-enzyme A from pantothenate but the yield was greatly increased when casein hydrolysate was added. Cystine or cysteine was as effective as the hydrolysate and glutathione had some effect, but β -mercaptoethylamine or its N- β -alanyl derivative, cysteic acid, homocystine, methionine, S-methylcystine, thioglycolic acid, thioacetamide or ethanethiol had none. There was no synthesis when glucose was omitted from the medium.

The amount of co-enzyme A formed by the cells was related to the initial content of the cells, those most deficient synthesising most.—V. R. Jackson.

BOXER, G. E., OTT, W. H. and SHONK, C. E. Influence of vitamin B₁₂ on the coenzyme A content of the liver of chicks. *Arch. Biochem. Biophys.*, 1953, **47**, 474-475. [Res. Labs., Merck and Co., Inc., Rahway, N.J.]

Co-enzyme A was measured by a modification of the method of Kaplan and Lipmann (Abst. 1921, Vol. 18) in the livers of chicks having a ration based on soya bean with or without a vitamin B₁₂ supplement. After 3, 5 and 7 weeks of the diets chicks deprived of vitamin B₁₂ had values for co-enzyme A about five times as great as those of chicks receiving the vitamin. After 7 weeks the results were confirmed by a phosphotransacetylase method. It is suggested that vitamin B₁₂ may be concerned in the conversion of pantothenic acid into co-enzyme A.—A. M. Copping.

GIROUD, A., LÉVY, G. and LEFEBVRES, J. Recherches sur le taux de l'acide pantothenique chez les mères et les foetus normaux et chez les mères carencées. [Pantothenic acid in normal mothers and foetuses and deprived mothers.] Une carence en acide folique engendre-t-elle chez la rate gestante une carence secondaire en acide pantothenique? [Does deprivation of folic acid cause secondary deficiency of pantothenic acid in the pregnant rat?] *Internat. Ztschr. Vitaminforsch.*, 1954, **25**, 148-153; 153-157. [Lab. Chim. Biol., Fac. Méd., Paris.] German and English summaries.

Adult female rats received a normal diet, or one deficient in pantothenic acid, from 6 days before mating and were killed after 21 days' gestation. Pantothenic acid was estimated in maternal and

N.A. and B., July 1954

foetal liver. In normal maternal livers the pantothenic acid content in $\mu\text{g.}$ per g. fresh tissue ranged from 63 to 137, average 90, and in normal foetal livers from 28.0 to 48.0, average 33.2. Foetuses from the same mother had similar values, and it is suggested that the differences between adults were due to differences in intestinal flora. In deprived rats the values for the maternal livers were from 40 to 60, average 52. The deficiency was severe and all foetuses were aborted. No sign of deficiency was seen in adult rats, which confirms that it is only with mild degrees of deficiency that malformation of foetuses can occur.

Pantothenic acid was estimated in livers of foetuses and pregnant rats that had received a diet deficient in folic acid with or without added folic acid, and with or without succinylsulphathiazole. All rats received 50 $\mu\text{g.}$ pantothenic acid daily. There was considerable variation among rats in any group, particularly in the group receiving the diet with folic acid but no antibiotic. Average pantothenic acid values in $\mu\text{g.}$ per g. fresh tissue were for maternal livers of the 4 groups, respectively, 60.1, 86.6, 85.4 and 92.2. Corresponding values for the foetuses were 27.5, 32.4, 27.6 and 33.7, so that, where folic acid was not available from diet or from intestinal synthesis, pantothenic acid in the maternal liver was reduced, but the reduction was not reflected in the foetal liver.—V. R. Jackson.

Rats given 20 or 30 mg. Pentothal per kg. body-

Vol. 24, No. 3

29, 566-569. [Lab. Biol., Ist. Superiore Sanità, Rome.]

Rats weighing from 50 to 60 g. were given a diet deficient in pantothenic acid, with or without addition of 100 mg. Ca pantothenate per kg. diet. The rats were killed from 30 to 35 or from 50 to 55 days later, when the deprived animals began to show signs of deficiency. The small intestine showed no histological change, and at post-mortem examination intestinal distension and lack of tone were very rare. There was no change in rhythm or in response to acetylcholine or adrenaline in the isolated intestine of the deprived rats, and addition of Ca pantothenate to the preparation had no effect. Response to eserine or prostigmine also was unaffected. The rate of passage of animal charcoal through the intestine was accelerated in the deprived rats.—E. M. Hume.

FOLIC ACID (PTEROYLGLUTAMIC ACID)

3075

- BRIGGS, G. M., SPIVEY, M. R. and ORTIZ, L. O. Variation of growth in successive experiments with folic acid-deficient chicks and the influence of aureomycin. *J. Nutrition*, 1953, **51**, 355-364. [Nat. Inst. Arthritis Metabol. Dis., Nat. Inst. Health, Bethesda, Md.]

In each of a series of 14 trials a group of 6 day-old New Hampshire pullets was housed in a wire-floored cage and given to appetite, for 4 weeks, a purified diet of casein, gelatine, methionine, maize oil, minerals, glucose and all identified vitamins with the exception of folic acid. Further groups received the same ration with the addition, per kg. diet, of 3 mg. folic acid, or 50 mg. aureomycin hydrochloride or both.

There were very few deaths of birds receiving folic acid, and the mean finishing weight of each group was within the range of from 330 to 410 g. without aureomycin, and of from 340 to 410 g. with aureomycin.

In the earlier half of the series deaths were infrequent among the chicks receiving no dietary supplement, and the depression of growth and other signs of folic acid deficiency were not severe; comparable groups receiving aureomycin showed more severe signs and were significantly lighter at 4 weeks of age. In the later half of the series more severe signs of deficiency appeared in the unsupplemented groups, and the inclusion of aureomycin had no effect.

The whole series of trials, which covered 18 months, took place in a house not previously used for poultry, and at the end of each experiment most, but not all, of the cages and equipment were sterilised in steam.—K. J. Carpenter.

Further studies were made of damage to the kidneys in guineapigs receiving large parenteral doses of folic acid (Abst. 1798, Vol. 20). The animals were maintained on a scorbutogenic diet with or without addition of ascorbic acid. Tests were made with solutions of pure crystalline pteroyl-

glutamic acid before or after exposure to sunlight. The lesions were produced by from 6 to 10 daily injections of 8 mg. pteroylglutamic acid, whether untreated or photolysed. No difference due to the presence of products of photolysis could be detected, and there was no difference whether ascorbic acid was given or not. Daily doses of 2 mg. pteroylglutamic acid produced lesions in a few animals.—A. M. Copping.

- BRODY, G. Use of the thymus gland in chicks to elucidate interrelationships between pteroylglutamic acid and biologically related substances. *Science*, 1953, **118**, 720-721. [Dept. Bacteriol., Michigan State Coll., East Lansing.]

Studies were made of the effect of pteroylglutamic acid, vitamin B₁₂, vitamin C and leucovorin on the weight of the thymus gland in chicks infected with *Ascaridia galli*. In absence of pteroylglutamic acid the thymus atrophied. Vitamin B₁₂ restored the gland only partly, but a combination of pteroylglutamic acid and vitamin B₁₂ was more effective than pteroylglutamic acid alone. Addition of vitamin C to the other two vitamins further stimulated development of the thymus. Leucovorin in an amount of 400 µg. per 100 g. diet was as effective as pteroylglutamic acid and vitamin B₁₂ together. The result supported the view that leucovorin is the active form of pteroylglutamic acid.—A. M. Copping.

Groups of mice deprived of folic acid were given for 8 days supplements of 10 µg. folic acid, with or without methanol and serine, or methanol and serine without folic acid. The mice were killed and choline and methionine were estimated in the

N.A. and R., July 1954

liver, and phosphocreatine in the muscles. Those given folic acid, or methanol and serine, showed an increase in choline, methionine and phosphocreatine over those given no supplements; those given all 3 showed the highest values except for phosphocreatine, the value for which was inferior to that when folic acid only was given. The results are discussed with reference to those of Verly *et al.* (Abst. 1997, Vol. 22), with which they are not in accord.—A. M. Copping.

SILVER, M. **The role of folic acid in hormonally-induced tissue growth.** *J. Endocrinol.*, 1953-1954, **10**, 95-110. [Nat. Inst. Res. Dairying, Univ. Reading.]

When folic acid deficiency was induced in female rats by means of aminopterin the growth of the mammary glands and uterus in response to a maximum dose of oestradiol dipropionate was considerably less than in pair-fed rats having no folic acid antagonist. The inhibition of the uterine response to oestrogen was less marked than that of the mammary gland. On administration to pigeons of a synthetic diet containing aminopterin, the growth of the crop gland in response to prolactin was decreased, though no signs of folic acid deficiency could be recognised. The response to prolactin was restored if folic acid or citrovorum factor was given at the same time as aminopterin. The results are discussed with reference to other reports on the relation of folic acid to hormone response.—A. M. Copping.

GOLDIN, A., MANTEL, N., GREENHOUSE, S. W., VENDITTI, J. M. and HUMPHREYS, S. R.

Vol. 24, No. 3

Estimation of the antileukemic potency of the antimetabolite aminopterin, administered alone and in combination with citrovorum factor or folic acid.

Effect of delayed administration of citrovorum factor on the antileukemic effectiveness of aminopterin in mice. *Cancer Res.*, 1953, **13**, 843-850; 1954, **14**, 43-48. [Lab. Chem. Pharmacol., Nat. Cancer Inst., Bethesda, Md.]

Male mice inoculated with lymphoid leukaemia received, 3 days after inoculation, subcutaneous injections of aminopterin alone, simultaneously, or with citrovorum factor or folic acid, or 1 hr. after folic acid. Deaths due to aminopterin occurred from 3 to 6 days after its administration and those due to the tumour from 13 to 16 days after inoculation. The results were examined statistically.

With all combinations of doses, as the amount of aminopterin increased, there was an increase in the mortality due to aminopterin and in the survival times in relation to the leukaemia after survival from the antivitamin.

When citrovorum factor was given with the aminopterin, or when folic acid was given 1 hr. before it, there was reduction in the mortality from the antivitamin and in the survival time relative to the same dose of aminopterin given alone. In groups with the same mortality from aminopterin, those receiving aminopterin alone survived longer than those receiving it with citrovorum factor or after folic acid. Folic acid given at the same time as aminopterin did not affect mortality or survival time.

In discussion it is suggested that the best results might be got by giving an ordinarily lethal dose of aminopterin followed by a massive dose of citrovorum factor before extensive damage to the host had been caused.

Another experiment was designed which showed that treatment of leukaemic mice with aminopterin, followed after from 12 to 24 hr. by citrovorum factor, was more effective in prolonging survival time than treatment with aminopterin alone. Citrovorum factor given at that time reduced the mortality due to aminopterin but did not reduce its antileukaemic action.

BUCHANAN, D. J., PEARSON, W. N., AMARASINGHAM, C., HUDSON, G. W. and DARBY, W. J.
Citrovorum factor and irradiation injury. *Amer. J. Physiol.*, 1953, **175**, 437-439. [Dept. Biochem., Sch. Med., Vanderbilt Univ., Nashville, Tenn.]

An increase of folic acid activity in the urine was found in rats exposed to X-rays (Abst. 4196, Vol. 23), so an attempt was made to control the effects of exposure by administration of citrovorum

factor, which is a highly active folic acid metabolite. Rats which received injections of 1 mg. citrovorum factor daily for 5 days before, and 28 days after, exposure showed no detectable difference in weight change, food intake or development of leucopenia, from rats having injections of saline or no treatment.—A. M. Copping.

FOLEY, G. E. and HALEY, E. C. **Synthesis of citrovorum factor by *Leuconostoc citrovorum*; potentiation by ascorbic acid.** *J. Bacteriol.*, 1953, **66**, 727. [Labs. Microbiol., Child. Cancer Res. Found., Harvard Med. Sch., Boston, Mass.]

Tests with washed buffered suspensions of *Leuconostoc citrovorum* showed that citrovorum factor was synthesised from pteroylglutamic acid in the presence of suitable concentrations of ascorbic acid.

Dihydropteroylglutamic acid could replace citrovorum factor in the absence of ascorbic acid or other reducing agents, and tests with dihydro- or formylated pteroylglutamic acid suggested that the need for a reducing agent was related intimately to the reduction of pteroylglutamic acid or its

formylated form in the synthesis or citrovorum factor by the organism.

It is thought that the reducing agents acted by direct activation of an enzyme system or by protection of a labile intermediate.—V. R. Jackson.

3086

JANDL, J. H. (with HIRSHBERG, E. A. and DeCARLI, L. M.) **Failure of cortisone and hydrocortisone to replace pteroylglutamic acid and citrovorum factor in microbial growth.** *Proc. Soc. Exp. Biol. Med.*, 1954, **85**, 166. [Thorndike Mem. Lab., Second and Fourth Med. Serv. (Harvard), Boston City Hosp., Mass.]

Streptococcus faecalis, *Lactobacillus casei* and *Leuconostoc citrovorum* were incubated in media with or without pteroylglutamic acid or citrovorum factor but with added cortisone, cortisone acetate or hydrocortisone in amounts ranging from 0.1 to 500 μ g. per ml.

No growth occurred in media without pteroylglutamic acid or citrovorum factor, and there was no enhancement of growth by the steroids when added to media with these vitamins, over a wide range of concentrations.—V. R. Jackson.

VITAMIN B₁₂

3087

VAN KLAVEREN, F. W. and SHRIVASTAVA, P. C. **The lead anaemia in the rabbit and the potency of liver extracts. 2.** *Internat. Ztschr. Vitaminforsch.*, 1954, **25**, 139–147. [Res. Dept., Teddington Chemical Factory, Ltd., Surén Rd., Andheri, Bombay.] German and French summaries.

In rabbits with lead anaemia, the haemopoietic effect of whole liver extracts was compared with that of vitamin B₁₂. The results agreed with those found by photometric estimation of the vitamin B₁₂ content of the liver extracts. The haemopoietic potency of the liver extract was extracted quantitatively by a mixture of phenol and chloroform; the aqueous residue was inactive. The biological and photometric methods both gave the content of the whole vitamin B₁₂ in the liver extract.—M. B. Richards.

3088

GAUDIANO, A. **Metodo per la determinazione chimica della vitamina B₁₂ negli estratti epatici. [Chemical method for estimating vitamin B₁₂ in liver extracts.]** *Boll. Soc. ital. Biol. sper.*, 1953, **29**, 471–473. [Lab. Biol., Ist. Superiore Sanità, Rome.]

The chief steps in the estimation were transformation of all forms of vitamin B₁₂ to cyano-

cobalamin by treatment with KCN, removal of impurities by means of butanol and a saturated solution of (NH₄)₂SO₄, extraction with water, reduction to dryness, ashing and, after other treatments including addition of α -nitroso- β -naphthol, estimation by spectrophotometry. The method was applicable to amounts of from 50 to 100 μ g. vitamin B₁₂ at concentrations of not less than 1 μ g. per ml.—E. M. Hume.

WIJMEGA, H. G., THOMPSON, K. W., STERN, K. G. and O'CONNELL, D. J. **Preparation and properties of a cobalamin protein.** *Biochim. biophys. Acta*, 1954, **13**, 144–146. [Labs. N. V. Organon, Oss, Netherlands.]

A complex of cobalamin with protein was obtained by combining crystalline vitamin B₁₂ with extracts of gastric mucosa from the pyloric region of the pig. A highly purified pink protein complex was isolated by electrophoretic analysis. The compound had well defined physicochemical properties and a molecular weight of about 100,000. It appeared to be a chemical compound, a cobalamin protein, and not an adsorption complex. The purified cobalamin protein did not appear to possess clinical haematological activity, but such activity was present in crude preparations in proportion to their vitamin B₁₂ potency. The

N.A. and R., July 1954

possible role of the purified cobalamin protein as a component of Castle's intrinsic factor is under investigation.—A. M. Copping.

ARMITAGE, J. B., CANNON, J. R., JOHNSON, A. W., PARKER, L. F. J., SMITH, E. L., STAFFORD, W. H. and TODD, A. R. **Chemistry of the vitamin B₁₂ group. 3. The course of hydrolytic degradations.** *J. Chem. Soc.*, 1953, 3849-3864. [Chem. Lab., Univ. Cambridge.]

Products of acid and alkaline hydrolysis of vitamin B₁₂ in a variety of conditions were examined by electrophoretic and chromatographic methods. The results suggested that vitamin B₁₂ contains at least 3 primary amide groups and probably one —CO·NH·CH₂·CHMeO— grouping. Fission of these groups would account for 4 of the carboxyl products obtained in hydrolysis with hot alkali. The amide linkage between aminopropanol and the rest of the molecule, previously suggested (Abst. 5071, Vol. 20), was confirmed. Alkaline hydrolysis with Ba(OH)₂ removed the 5:6-dimethylbenzimidazole nucleotide from the molecule. The nucleotide was isolated in free crystalline form by electrophoretic separation from the cobalt-containing pigment. The stable end-products of strong acid and alkaline hydrolysis contained Co and from 5 to 7 acidic groupings.

MÁNYAI, S. **Stoffwechseleränderungen im Laufe der Entwicklung der roten Blutkörperchen. 1. Untersuchungen mit dem Blut verschieden alter Ratten. [Metabolic changes during the development of red blood cells. 1. Experiments with the blood of rats of different ages.]** *Acta physiol. hung.*, 1954, 5, 19-29. [Med. Chem. Inst., Med. Univ., Budapest.] Russian summary.

Adenosinetriphosphate (ATP), the glycolytic activity of the red cells, and the size of the red cells, were estimated in blood from 325 rats of ages from newborn to 12 months. In suckling rats ATP ranged from 1890 ± 640 to 4610 ± 910 µg. per ml. red cells, with correspondingly high production of lactic acid. From about 8 weeks of age the values fell to adult levels of about 800 µg. ATP per ml. and of from 8725 to 990 µg. lactic acid per ml. The mean diameter of the red cells was greater in young rats, and fell from 9.93 µ. at birth to 6.21 µ. at a year. The packed cell volume at maturity was only one-quarter of that of newborn animals.

In a second experiment the effect of vitamin B₁₂ on the blood of rats was investigated in 55 young from mothers on a stock diet and in 54 young from mothers having a supplement of vitamin B₁₂ during pregnancy. In the latter the ATP content of the whole blood and of the red cells, and the size of the red cells, were significantly less than in the rats with no vitamin B₁₂.—A. M. Copping.

GEBAUER, H. **Histologische Veränderungen in Milz und Leber von Albinoratten nach Vitamin B₁₂-gaben und Kobaltfütterung. [Histological changes in the spleen and liver in albino rats after vitamin B₁₂ and cobalt administration.]** *Naturwissenschaften*, 1953, 40, 558-559. [Anst. Vitaminforsch., Potsdam-Rehbrücke.]

The paper is a summary of work to be published in detail in *Vitamine und Hormone*.

The point of attack of vitamin B₁₂ and of Co was studied with young rats weighing about 130 g. and with fully grown rats. Vitamin B₁₂ was given by intramuscular injection or by mouth, 0.5 µg. daily or more, and Co was given, 0.05 µg. per kg. bodyweight, as CoCl₂ or other compounds. The spleen reacted by vacuolisation of lymphocytes, opening-up of the malpighian bodies, especially the border zones, liberation and increased destruction of lymphocytes, and formation of numerous megacaryocytes (giant cells).

In the liver the Kupffer star cells also showed changes. The nuclei were bleached and, especially with Co, divided into clusters of up to 8 cells. Mitotic and amitotic cell-division took place in the liver parenchyma.

Rats from which the spleen was removed survived for only 3 weeks when given vitamin B₁₂ daily, or 6 weeks when given Co and vitamin B₁₂. Their livers showed cloudy swelling, pyknosis, caryorrhexis and finally caryolysis. There were fine precipitates of Fe, differently situated when Co was given from when vitamin B₁₂ was given.

LING, C. T. and CHOW, B. F. **The influence of vitamin B₁₂ on carbohydrate and lipid metabolism.** *J. Biol. Chem.*, 1954, **206**, 797-805. [Dept. Biochem., Sch. Hyg. Pub. Health, Johns Hopkins Univ., Baltimore, Md.]

Blood sugar, glucose tolerance and phospholipins in blood and tissues were measured in rats reared on diets deficient in vitamin B₁₂ with and without addition of vitamin B₁₂. Deprivation of vitamin B₁₂ caused a fall of blood sugar and disturbance of glucose tolerance. The phospholipin content of the whole body and of the blood and tissues per unit of weight was much less in those deprived of vitamin B₁₂. A low value for phospholipin was found in the blood of 2 patients with pernicious anaemia and an increase occurred after administration of vitamin B₁₂. When rats were given high-carbohydrate diets and injections of glucose the resulting hyperglycaemia was reduced transiently by subcutaneous injection of glutathione and more markedly by injection of vitamin B₁₂; the glutathione content of the blood was low in the hyperglycaemic rats and also in rats deprived of vitamin B₁₂.

The relation between glutathione and vitamin B₁₂ in fat and carbohydrate metabolism is discussed.—A. M. Copping.

REGISTER, U. D. **Effect of vitamin B₁₂ on liver and blood non-protein sulphhydryl compounds.**

J. Biol. Chem., 1954, **206**, 705-709. [Dept. Biochem., Sch. Med., Coll. Med. Evangelists, Loma Linda, Calif.]

Weanling rats from mothers deprived of vitamin B₁₂ during pregnancy and lactation were given diets with soya bean meal as source of protein with or without addition of vitamin B₁₂. After 5 weeks they were killed and total sulphhydryl groups, glutathione and ergothioneine were estimated in the liver and red blood cells. The rats having no vitamin B₁₂ had less sulphhydryl compounds, especially glutathione, in the liver and blood. There was little difference in the ergothioneine content, which was one-tenth or less of the glutathione content. A diet containing maize-meal and soya bean meal gave higher values for total sulphhydryl groups than one containing soya bean meal and dextrose. The role of glutathione in enzyme systems concerned with fat and carbohydrate metabolism is discussed with reference to the effects of vitamin B₁₂ on the glutathione content of the liver and blood.—A. M. Copping.

Groups of weanling female rats receiving a purified diet with soya bean flour as source of protein grew equally well with or without addition of 100 µg. vitamin B₁₂ per kg. diet during 12 weeks at a room temperature of about 23° C. When rats on the same two diets were kept at 2° C., 15 out of 20 having vitamin B₁₂ survived with an average weight increase of 93.5 ± 4.9 g.; of those having no vitamin B₁₂, 14 out of 20 survived with an average weight increase of 69.8 ± 3.0 g. which was significantly less than in the other group. Litters obtained from the rats kept at room temperature were given the experimental diets at weaning and those bred and reared on the diet without vitamin B₁₂ died during the first 96 hr. of exposure to the low temperature, 30 days after weaning.—A. M. Copping.

3102

CALET, C., RERAT, A. and JACQUOT, R. **Signification des relations entre auréomycine et vitamine B₁₂.** [Significance of the relations between aureomycin and vitamin B₁₂.] Essai d'interprétation du rôle de l'auréomycine comme facteur de croissance. [Interpretation of the role of aureomycin as growth factor.] *C.R. Acad. Sci.*, 1954, **238**, 938-940; 1071-1073.

With a basal diet containing per cent. white flour 85, arachis oil 8, and salt mixture 4, with all vitamins except vitamin B₁₂, the growth of rats was not improved by vitamin B₁₂ but was considerably increased by aureomycin. Vitamin B₁₂ with aureomycin was no more effective than aureomycin alone. The vitamin B₁₂ content of the livers was not raised in rats given aureomycin.

In a further study of the effect of aureomycin on weight gain and utilisation of food by rats on a complete, purified diet, it was shown that aureomycin was more effective alone than with vitamin B₁₂. The greater weight gain was not caused by improved digestibility or by increased retention of water or protein, but appeared to be due to early deposition of fat.—A. M. Copping.

3103

BURNSIDE, J. E., GRUMMER, R. H., PHILLIPS, P. H. and BOHSTEDT, G. **The influence of crystalline aureomycin and vitamin B₁₂ on the protein**

Vol. 24, No. 3

utilization of growing-fattening swine. *J. Animal Sci.*, 1954, **13**, 184-200. [Dept. Animal Husb., Univ. Wisconsin, Madison.]

The effect was studied of adding 20 µg. vitamin B₁₂ and 20 mg. aureomycin per kg. diet, singly or together, on the rate of weight gain, efficiency of feed utilisation, Hb, and plasma protein, of weanling pigs growing to an average bodyweight of 213 lb. on basal diets containing initially 21, 17 and 12.6 per cent. protein. The protein came from maize, soya bean meal and alfalfa meal and the percentage in the diets was reduced, respectively, to 17, 13.7 and 10.4 when the groups averaged 70 lb., and to 15, 11.5 and 9.8 at 126 lb.

In these conditions vitamin B₁₂ alone had little or no effect on the growth or blood picture of the pigs. Aureomycin alone did not improve growth in the pigs having the high protein intake but in those with medium or low protein intake it improved the performance, judged by growth and blood picture. In the group having high protein, aureomycin alone appeared to be slightly detrimental, especially after the pigs weighed 70 lb., when an increased need for vitamin B₁₂ seemed to arise. Aureomycin and vitamin B₁₂ together improved utilisation of protein in all groups. Significant correlations between growth and blood constituents were found for all groups.

A. M. Copping.

HALBROOK, E. R., BEECKLER, A. F. and SMITH, E. P. **The value of fish solubles and a vitamin B₁₂-antibiotic supplement in chicken and turkey mash mixtures containing ten per cent. meat scraps.** *Poultry Sci.*, 1953, **32**, 1058-1068. [Dept. Poultry Indust., Montana State Coll., Bozeman.]

In a trial lasting 16 months 4 rations were tested with chicks, and poults, from day-old through their first laying year. One ration was of meat scraps (55 per cent. protein) 10, soya bean meal 15, alfalfa meal 10, ground wheat 40, ground oats 20, minerals, fish oil and riboflavin; another had the same composition except that the cereals were yellow maize meal 20, ground wheat 10, ground oats 10, wheat middlings 10 and wheat bran 10. Each of the rations was given alone or with 3 per cent. condensed fish solubles added at the expense of the soya bean meal.

The birds were kept for 12 weeks in electric brooders with litter on the floor, then transferred to alfalfa range and finally brought back into laying pens with litter floors at 24 weeks of age. Each ration was given to one group of 250 New Hampshires, one of 250 White Leghorns, and one of 100 Bronze poults.

At no point did the difference in cereals used appear to affect performance. At 12 weeks of age

the groups receiving fish solubles were from 1 to 6 per cent. heavier than those without. The males killed at 12 weeks as broilers did not significantly differ in carcase quality through the different treatments. At 24 weeks the pullets receiving fish solubles were not significantly heavier than those without, nor was their egg production or the hatching capacity of the eggs consistently affected.

A further trial of similar design was made but 0.02 p.p.m. vitamin B₁₂ and 20 p.p.m. aureomycin were added to the rations instead of the fish solubles. At 12 weeks chicks of both breeds receiving this supplement were, respectively, 5 and 11 per cent. heavier than those without it, and the respective average percentage mortality was 4.4 compared with 9.8 for the unsupplemented groups. The poultts receiving the supplement were 17 per cent. heavier than those without, and the total percentage mortality was 9.5 compared with 24.3 for those without supplement. The males were again marketed as broilers at 12 weeks; in market grading the chickens appeared to benefit from the supplement, but the poultts were, if anything, adversely affected. During the next 12 weeks the pullets lost most of the extra weight attributed to the supplement and the percentage mortality was 6.8 in the groups with supplement compared with 4.6 in those without. In the laying period there was no evidence of any effect of the supplement on egg production or mortality. Hatching capacity was slightly less in the groups with the supplement.

At 6 months of age the breeding turkeys that received the supplement of vitamin B₁₂ and aureomycin were 5 per cent. heavier than those without, but egg production and hatching capacity were, respectively, 12 and 7 per cent. less than for those without. There was no difference in mortality.

It is concluded that the study provided no evidence to support the use of vitamin B₁₂ and an antibiotic as supplement for replacement pullets and laying birds with the basal rations and management used.—K. J. Carpenter.

3105

GORDON, R. F., CHUBB, L. G. and STACEY, C. G. **Vitamin B₁₂ and penicillin supplements in poultry nutrition.** *Vet. Rec.*, 1954, **66**, 71-74. [Poultry Res. Stat., Animal Health Trust, Houghton Grange, Huntingdon.]

Groups of 50 crossbred chicks were reared intensively on sawdust litter, which was changed weekly. They received an adequate standard ration of oats, wheat and wheat middlings, maize and maize gluten feed, grassmeal, white-fish meal, dried milk, dried yeast, minerals, vitamin D and riboflavin, with or without vitamin B₁₂ or penicillin or both, or the standard ration modified by

replacing the fishmeal wholly or partly by groundnut meal, with or without the addition of a supplement of vitamin B₁₂. At 16 weeks of age the cockerels were killed and the pullets transferred to laying cages. Dried milk was omitted from the rations.

The addition of penicillin to the standard ration did not improve growth or the production and hatching capacity of the eggs. When the ration contained groundnut meal and added vitamin B₁₂ growth was not as good as when as little as 5 per cent. fishmeal was the source of protein. On a solely vegetable diet, fewer eggs were produced than on a diet containing animal protein and a supplement of vitamin B₁₂ conferred no advantage. Addition of vitamin B₁₂ and penicillin to the standard ration did not increase production. The hatching capacity of eggs from caged pullets was increased by a vitamin B₁₂ supplement but was less than on a ration containing fishmeal. The addition to the standard ration of both penicillin and vitamin B₁₂ slightly increased the percentage of fertile eggs which hatched.—E. M. Cruickshank.

3106

CARLSON, C. W., JONES, D. G., KOHLMAYER, W. and MOXON, A. L. **The effects of vitamin B₁₂ and aureomycin on reproductive performance in turkeys.** *Poultry Sci.*, 1953, **32**, 984-989. [S. Dakota Agric. Exp. Stat., College Station.]

Twenty-five turkey hens, about 30 weeks of age, and 2 toms, were housed in each of 4 breeding pens which were floored with deep straw litter and opened on to a cobblestone yard. For the next 17 weeks all the pens received a diet of soya bean meal 13, alfalfa meal 3, yellow maize meal 40, ground oats 29, wheat standard middlings 10, minerals and riboflavin. One pen received no supplement, and the other 3 received, per kg. diet, 11 mg. aureomycin hydrochloride or 8.8 µg. vitamin B₁₂ or both.

There were only small differences between the pens in egg production, fertility and hatching capacity. For the 4 treatments the numbers of poultts obtained per 100 hen-days were 25.7, 25.8, 26.4 and 27.6 per cent., respectively.

When the poultts were reared on rations rich in vitamin supplements their rate of growth appeared to be independent of the diet on which the dams were fed. With less well fortified starter rations the progeny of dams receiving the supplemented diets gave slightly faster growth to 4 weeks of age, but the results of 2 different hatches were not consistent.—K. J. Carpenter.

FRÖLICH, A. **Relation between the quality of soybean oil meal and the requirements of**

N.A. and R., July 1954

vitamin B₁₂ for the chicks. *Nature*, 1954, **173**, 132-133. [Nat. Animal Exp. Stat., Upsala.]

Irregularities in the response of chicks to pure vitamin B₁₂ suggested that the quality of the soya bean oil meal used in the basal diet had to be examined. Three samples of meal were tested for antiproteolytic activity, percentage of water-soluble protein, urease activity, formaldehyde titration and phenolphthalein adsorption. The tests showed that 2 of the meals had not been sufficiently heated and were of poor quality. In growth experiments with chicks these 2 samples gave a less satisfactory response than the third, which contained little water-soluble protein and had no antiproteolytic activity. With meals of poor quality the requirement for vitamin B₁₂ appeared to be increased.—A. M. Copping.

WOLFF, R. and KARLIN, R. Sur la combinaison du sérum de quelques mammifères avec la vitamine B₁₂. [Combining power of the serum of some mammals with vitamin B₁₂.] *Bull. Soc. Chim. biol.*, 1953, **35**, 1409-1413. [Lab. Chim. Biol., Fac. Méd., Nancy.]

Free and total vitamin B₁₂ was estimated with *Lactobacillus leichmannii* in untreated serum and in serum autoclaved in the presence of cyanide. The different species studied were rabbit, sheep, goat, horse, calf, dog and pig. The values for rabbit blood were the highest, average 43.3 μg . per ml. Vitamin B₁₂ in the serum appeared to be bound in a thermolabile protein complex which could combine with further vitamin B₁₂ added *in vitro*. Only when vitamin B₁₂ was present in

excess of the amount which the protein could bind was there free vitamin B₁₂ in the blood.

KARLIN, R. and WOLFF, R. Répartition de la vitamine B₁₂ dans le sérum sanguin de quelques mammifères. [Distribution of vitamin B₁₂ in the blood serum of some mammals.] *C.R. Soc. Biol.*, 1953, **147**, 1387-1389. [Inst. Bactériol., Lyons.]

The vitamin B₁₂ content of blood serum was estimated with *Lactobacillus leichmannii* in serum autoclaved at pH 5.1 to liberate the vitamin from its protein complex. The average values obtained in μg . per ml. were for rabbit 43.2, sheep 4.5, horse 3.16, guineapig 1.44, ox 0.34 and pig 0.32. The range of values for individuals of the same species was very wide.—A. M. Copping.

3110

SCHENDEL, H. E. and JOHNSON, B. C. Feed from sewage. Activated sewage sludge as a source of vitamin B₁₂ for the pig. *J. Agric. Food Chem.*, 1954, **2**, 23-24. [Div. Animal Nutrit., Univ. Illinois, Urbana.]

Addition of 2 per cent. dried, activated sewage sludge to a synthetic milk containing alpha-protein from soya bean improved growth and feed utilisation in baby pigs to the same extent as an adequate supplement of 0.5 μg . vitamin B₁₂ per kg. body-weight. The dried sludge contained 3.11 μg . vitamin B₁₂ activity per g. and during the 5-week test period inclusion of sludge in the diet appeared to do the little pigs no harm.—A. M. Copping.

OTHER B VITAMINS

3111

FRENCH, E. W. and FRAENKEL, G. Carnitine (vitamin B_T) as nutritional requirement for the confused flour beetle. *Nature*, 1954, **173**, 173. [Dept. Entomol., Univ. Illinois, Urbana.]

Larvae of the flour beetle, *Tribolium confusum*, Duval, received a diet containing casein 50, glucose 50, cholesterol 1, and salt mixture 1 part, vitamins B₁ and B₆, riboflavin, nicotinic, pantothenic and folic acids, choline, biotin and inositol with or without supplements of whole yeast or a water-soluble fraction of it or carnitine (vitamin B_T). Larvae in groups with or without the supplements had similar weights, survival times and times to pupation, and the pupae were similar. Most adults without supplements died soon after emergence, before tanning and hardening of the cuticle, but those with supplements were normal.

It is concluded that carnitine is a dietary essential for *Tribolium confusum*.—V. R. Jackson.

Vol. 24, No. 3

3112

LECLERCQ, J. Action vitaminique de la "DL-dicarnitine" chez "Tenebrio molitor L" (insecte, coléoptère). [Vitamin action of DL-dicarnitine in *Tenebrio molitor*, L. (Insecta, Coleoptera).] *Arch. internat. Physiol.*, 1954, **62**, 101-108. [Inst. Léon Fredericq, Univ. Liège.]

Two strains of *Tenebrio molitor* larvae, F and G, received the synthetic diet described by Fraenkel *et al.* (Abst. 1587, Vol. 20) slightly modified, with or without the addition of "dicarnitine", a dimer of carnitine.

All larvae deprived of dicarnitine died within 10 weeks, generally after from 4 to 6 weeks, with signs of carnitine deficiency. Of the larvae receiving dicarnitine, of strain F 20 per cent. and of strain G 65 per cent. died within 10 weeks; they were not pigmented and showed signs like those in deprived larvae. Weights of the surviving nymphs were less than of those on natural diet. A number

survived to metamorphosis but, at this stage, mortality was similar in the 2 strains, 54 and 59 per cent. Nymphs of strain F which survived gave rise to abnormal adult forms and of strain G to normal forms. The results differed from those obtained by Fraenkel with carnitine, but it could not be stated whether the discrepancy was due to difference between the properties of carnitine and dicarnitine, to toxicity of the amount of biotin used in the diets, or to difference in sensitivity of the strains of *Tenebrio* employed.—V. R. Jackson.

3113

VERLY, W. G. and BACQ, Z. M. Prise oralement, la "dicarnitine" racémique n'est pas un bon donneur de méthyl pour le rat. [**Racemic dicarnitine, given orally, is not a good methyl donor for the rat.**] *Biochim. biophys. Acta*, 1954, **13**, 454-455. [Lab. Pathol. Gén., Univ. Liège.]

Weanling albino rats received for 5 days a complete basal diet as described by Du Vigneaud *et al.* (Abst. 4604, Vol. 9) and then in 4 groups received for 8 days the complete diet, or the diet with methionine replaced by homocystine alone or with choline or racemic dicarnitine. Racemic dicarnitine was formed by esterification of 2 molecules of carnitine (vitamin B_T), one acting as alcohol and the other as acid. All rats received vitamin B₁₂.

Rats having the complete diet containing methionine or the diet with homocystine and choline grew well. Growth of those having homocystine alone or with racemic dicarnitine stopped as soon as they received those diets; some died and in others growth recommenced after from 12 to 16 days, presumably because of synthesis of labile methyl groups. Post-mortem examination showed that rats having the complete diet or the diet with homocystine and choline were macroscopically normal; those in the other groups had enlarged livers and lesions in the kidneys. It is concluded that racemic dicarnitine is not a good methyl donor for the rat.—V. R. Jackson.

3114

FRAENKEL, G. Studies of the distribution of vitamin B_T (carnitine). *Biol. Bull.*, 1953, **104**, 359-371. [Dept. Entomol., Univ. Illinois, Urbana.]

Finely ground, dried powders or extracts of animal and vegetable matter were added to a synthetic diet and the rate of growth of *Tenebrio* larvae was recorded. If the survival of the larvae reached the optimum, and the larvae attained an average weight of 60 mg. after from 9 to 10 weeks at 30° C. and 60 per cent. relative humidity, the vitamin B_T (carnitine) content of the diet was taken to be 0.35 mg. per g. dry diet. This criterion was satisfied by from 1 to 4 per cent. of dried

brewer's yeast, *Torula utilis* or *Neurospora*, in the diet. *Bacterium coli* and *Tetrahymena geleii* had no carnitine activity; *Streptococcus haemolyticus* showed some activity when included as 1.25 per cent. Wheat had good activity as from 2.5 to 5 per cent. of the diet and spray-dried alfalfa juice as 1.8 per cent. Maize, rye and oats were inactive. Extracts from larvae deprived of carnitine had no vitamin B_T activity; extracts from larvae grown on an optimum diet of wholemeal flour and 5 per cent. yeast gave optimum survival in an amount equivalent to 2 per cent. of dried larvae. It is calculated that larvae retained half of the total intake of carnitine during life. Further, similar tests showed that larvae receiving synthetic diets and amounts of carnitine graded from 1.5 to 50 µg. per g. retained all the carnitine ingested. It is concluded that *Tenebrio* larvae do not synthesise carnitine.

Both *Dermestes vulpinus* and *Phormia regina* grew well on synthetic diets without added carnitine. Extracts from both gave good results with *Tenebrio*, showing that they synthesised carnitine. There was no carnitine in the hen's egg, but a considerable amount in the developing embryo. In dried dog, rat and rabbit tissue the quantities were largest in skeletal muscle with about 1000 µg. per g.; other values ranged from 35 in dried blood to 560 in heart. Paralysis of muscle for several weeks and autolysis of liver did not affect the values. Human whole blood or plasma contained 7 to 14 µg. per ml. and urine from 14 to 264, the highest values being found after ingestion of meat. Meat extracts contained from 1 to 3 per cent. carnitine on dry weight; fish extracts and yeast, including vitamin T (Pharmazell), contained considerably less.—V. R. Jackson.

3115

RABBI, A., PICCIONI, M. and MORUZZI, G. Aspetti della carenza del FPA della caseina nel ratto. [**Aspects of the lack of animal-protein factor in casein in the rat.**] *Boll. Soc. ital. Biol. sper.*, 1953, **29**, 552-553. [Ist. Chim. Biol., Univ. Bologna.]

It is stated that the deficiency caused in rats by the diet of Randoin and Causeret (Abst. 3159, Vol. 17), when the casein is purified, gives rise in the first generation, at the age of about 7 months, to cancerous or precancerous growths in the mammary glands, peritoneum and lungs (see also Title 1851, Vol. 24).—E. M. Hume.

3116

TOMIYAMA, T. and YONE, Y. A new chick growth promoting factor in liver. *Proc. Japan Acad.*, 1953, **29**, 178-182. [Dept. Fishery Chem., Fac. Agric., Univ. Kyushu.]

N.A. and R., July 1954

A factor called vitamin B15 was prepared as a concentrate by adsorption from a solubilised beef-liver filtrate on activated charcoal at pH 4. The charcoal was washed with dilute HCl and the factor was eluted with dilute NaOH. The concentrate had growth-promoting action for chicks on a

vegetable protein diet over and above the effects of vitamin B₁₂ and folic acid. It also increased the efficiency of feed utilisation in the chick. Some preliminary evidence is presented for the existence of other new growth factors in liver.

A. M. Copping.

VITAMIN C (ASCORBIC ACID)

3117

KING, C. G. **The discovery and chemistry of vitamin C.** *Proc. Nutrition Soc.*, 1953, **12**, 219-227. [Nutrition Foundation, Inc., Chrysler Bldg., New York.]

3118

SETNIKAR, I. and POIDOMANI, M. Dosaggio dell'acido ascorbico e del deidrosascorbicone su un medesimo campione biologico. [Estimation of ascorbic acid and of dehydroascorbic acid in the same biological sample.] *Boll. Soc. ital. Biol. sper.*, 1953, **29**, 549-552. [Lab. Fisiol., Univ. Milan.]

Ascorbic acid was estimated by the methylene blue method of Martini and Bonsignore (Abst. 2197, Vol. 4). It was then oxidised to dehydroascorbic acid and estimated by the method of Roe and Kuether (Abst. 261, Vol. 13) as modified by Meyer *et al.* (Abst. 1709, Vol. 23).—E. M. Hume.

3119

SPANYÁR, P. **The significance of reductones at the biological appraisal of foods.** *Acta chim. hung.*, 1953, **3**, 395-412. [Inst. Res. Canning, Meat Packing and Refrigeration, Budapest.] Russian and German summaries.

The $\alpha\alpha'$ -dipyridyl method of Schulek and Floderer (Abst. 334, Vol. 10) was considered to give the most satisfactory measure of the vitamin C content of foods. The only difficulty was interference from the presence of reductones, which was eliminated by carefully controlled treatment with formaldehyde. The results obtained by the $\alpha\alpha'$ -dipyridyl method for 17 fruits, vegetables and food preparations were compared with results from the dinitrophenylhydrazine method, and found to vary somewhat in the assessment of ascorbic acid and reductones.

The reductones formed during processing and storage of canned foods were investigated, especially those associated with enzymic browning. Reductones formed in foods with high amino-acid content were dark in colour. The pH value of solutions decreased during reductone formation but the extent of the pH change was not related to the amount of reductone formed. The presence of phosphate increased reductone formation.

Vol. 24, No. 3

Reductones were capable of forming osazones which gave coloured solutions with H₂SO₄, but the colour intensity was less than that of the osazone of dehydroascorbic acid.—A. M. Copping.

3120

MITCHELL, L. C. and PATTERSON, W. I. **The separation and identification of L-ascorbic, D-isoascorbic and D-glucosascorbic acids by paper chromatography.** *J. Assoc. Off. Agric. Chem.*, 1953, **36**, 1127-1130. [Dept. Health, Washington 25, D.C.]

Pure L-ascorbic, D-isoascorbic and D-glucosascorbic acid in mixtures were separated by chromatography on paper impregnated with 1 per cent. metaphosphoric acid, and air-dried. The mobile solvent was a mixture of acetonitrile, acetone, water and glacial acetic acid in the proportion of 80:5:15:1. The spots were detected by spraying with ammoniacal silver nitrate. In these conditions dehydroascorbic acid did not show a spot.—W. Godden.

3121

HUELIN, F. E. **Studies on the anaerobic decomposition of ascorbic acid.** *Food Res.*, 1953, **18**, 633-639. [C.S.I.R.O., Div. Food Preservation, Homebush, N.S.W.]

The anaerobic decomposition of pure ascorbic acid in citrate-phosphate buffer solutions over the pH range 2.2 to 6.0 was studied at 30° and 100° C. The values for ascorbic acid were corrected for "apparent ascorbic acid" by the method of Wokes *et al.* (Abst. 277, Vol. 14). Decomposition occurred most rapidly at pH from 3 to 4 at both temperatures, and was accelerated by the presence of fructose and its 6-phosphate and 1:6-diphosphate. There was some effect with sucrose, apparently due to the liberation of fructose. At high temperature and low pH the main products of decomposition were furfural and CO₂. The results are discussed in relation to the retention of ascorbic acid in canned fruits and vegetables.

W. Godden.

LÜCK, H. **Der Einfluss von komprimiertem Kohlendioxyd und Sauerstoff auf das Vitamin C.** [Effect of compressed carbon dioxide and

oxygen on vitamin C.] *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1954, **98**, 18-25. [Dairy Indust. Control Board, Windhoek, S. Africa.]

Vitamin C in lemon juice was rapidly broken down under CO₂ at 8 atmospheres pressure and 4° or 20° C. unless the CO₂ was free from O₂ and all air had been removed from the vessel. Hydrogen peroxide could be detected among the reaction products and produced an unsatisfactory aroma. Ascorbic acid was very rapidly destroyed under compressed oxygen at 4° and 20° C. One of the products was dehydroascorbic acid but the reaction was a complicated one in which a balance was established with other reaction products.

ISHERWOOD, F. A., CHEN, Y. T. and MAPSON, L. W. Synthesis of L-ascorbic acid in plants and animals.

Isolation of D-glyceric acid from cress seedlings and its relationship to the synthesis of L-ascorbic acid.

MAPSON, L. W., ISHERWOOD, F. A. and CHEN, Y. T. Biological synthesis of L-ascorbic acid: the conversion of L-galactono-γ-lactone into L-ascorbic acid by plant mitochondria. *Biochem. J.*, 1954, **56**, 1-15; 15-21; 21-28. [Low Temp. Res. Stat., Univ. Cambridge.]

Previous investigations have led to the probability that L-ascorbic acid is synthesised from a hexose which may be D-glucose. The authors have sought to ascertain the nature of the hexose precursor and the mechanism by which D-glucose or D-galactose might be transformed into L-ascorbic acid. Seven schemes are set out by which the transformation might theoretically take place. The one preferred derives L-ascorbic acid from D-glucose by oxidation to D-glucurono-γ-lactone, from which by inversion of configuration and reduction L-gulono-γ-lactone is formed, and from it by oxidation L-ascorbic acid can be derived. By a similar scheme D-galactose could be the original hexose. The schemes were tested by supplying the various compounds postulated as possible intermediates to cress seedlings and to rats. Positive results were obtained with 4 such substances. The results have been briefly reported already (Abst. 2999, Vol. 23).

The 3-carbon compound, D-glyceric acid, was isolated from cress seedlings but was shown not to be a precursor of L-ascorbic acid, though its synthesis was in some way coupled with that of L-ascorbic acid. In rats given chloretone synthesis of ascorbic acid is increased, and it was found that urinary excretion of D-glyceric acid was at the same time doubled. When 100 mg. each of ethyl DL- and D-glycerate were injected subcutaneously into rats, there was no increase in excretion of L-ascorbic acid.

Washed mitochondria were prepared from soaked pea seeds at a stage when oxidase activity would be low. The preparation catalysed the formation of L-ascorbic acid from L-galactono- γ -lactone, but not from L-gulono- γ -lactone or from D-mannono- γ -lactone. The effect of different conditions and substances on the synthesis was studied.

HAGEN, P. **The distribution of ascorbic acid between the particulate and non-particulate components of adrenal and liver cells.** *Biochem. J.*, 1954, **56**, 44-46. [Dept. Pharmacol., Univ. Oxford.]

The preparations were made from ox adrenal glands and dog's liver. The tissues were homogenised and dispersed in ice-cold 0.25 *M* sucrose solution. Fractions were separated by centrifuging at different speeds, and were tested for ascorbic acid by the method of Bessey (Abst. 4625, Vol. 8). From 87 to 100 per cent. of the ascorbic acid in the tissues was in the supernatant fraction from the high-speed centrifuging. There was almost none in the cytoplasmic particles. Resuspended mitochondria from the preparations did not stain black with silver nitrate.

BACCHUS, H. and HEIFFER, M. H. **Carbohydrate metabolism in ascorbic acid deficiency.** *Amer. J. Physiol.*, 1954, **176**, 262-266. [Dept. Physiol., Sch. Med., George Washington Univ., Washington, D.C.]

In guineapigs given a scorbutogenic diet or the same diet with green food, but with the intake regulated to that of those without green food, insulin tolerance tests and glucose-insulin tolerance tests showed that a progressive resistance to the action of insulin on blood sugar accompanied ascorbic acid deficiency. Similar tests with adrenalectomised animals on a scorbutogenic diet gave similar results. It is concluded that the disturbance of carbohydrate metabolism occurring in ascorbic acid deficiency is probably not due to diminished insulin secretion or to adrenal hyperactivity.—W. Godden.

3134

ALLEGRETTI, N. **Pancreatic islet cells and ascorbic acid in guinea pigs.** *Internat. Ztschr. Vitaminforsch.*, 1954, **25**, 125-135. [Inst. Physiol., Fac. Med., Univ. Zagreb, Yugoslavia.] German and French summaries.

Groups of guineapigs were fed on a diet of autoclaved beet, free from vitamin C, to which were added amounts of ascorbic acid ranging from 0.125 to 2.0 mg. daily. Three criteria were used to assess the degree of scurvy, namely, bodyweight change, tooth protection and ratio of beta to alpha cells in the islets of Langerhans. It was shown mathematically that the curves obtained were parallel but that the most precise measure of intake was obtained from the ratio of beta to alpha cells.—W. Godden.

IMAZUMI, R. and YOSHIDA, H. **Interrelation between adrenaline, ascorbic acid and amino acid.** 1. Interpretation between adrenaline and ascorbic acid, and also between adrenaline and amino acid; especially studies on adrenaline sensibilization by amino acid and ascorbic acid, and on the mechanism of adrenaline action.

IMAZUMI, R., YOSHIDA, H., SATO, H. and NODA, T. 2. Relationship between ascorbic acid and amino acid. *Med. J. Osaka Univ.*, 1953, **4**, 115-126; 127-134. [Dept. Pharmacol., Med. Sch., Univ. Osaka.]

1. From spectroscopic measurements of mixtures of adrenaline quinone with ascorbic acid, and from blood pressure tests for adrenaline in healthy adult rabbits, it was concluded that the adrenaline quinone was reduced to adrenaline in presence of ascorbic acid and that the ascorbic acid was oxidised in the process.

In similar experiments with glycine instead of ascorbic acid, the adrenaline quinone was reduced to adrenaline and there was oxidative deamination of the glycine.

2. By estimation of oxygen consumption, and with chemical and spectrophotometric methods, it appeared that the auto-oxidation of ascorbic acid was inhibited by glycine in acid solution and promoted in alkaline. Glycine was deaminated by ascorbic acid and more strongly by dehydro-ascorbic acid, which was at the same time reduced.

FORNABOLLI, P. and AMATI, A. Azioni dell' ATP sul contenuto in acido ascorbico del surrene in ratti integri. [Effects of adenosinetriphosphate on the ascorbic acid content of the adrenal gland in intact rats.]

KOLLER, M. and AMATI, A. Azione dell' ATP sul contenuto in acido ascorbico del surrene di ratti ipofisectomizzati. [Effect of adenosinetriphosphate on the ascorbic acid content of the adrenal gland in hypophysectomised rats.] *Boll. Soc. ital. Biol. sper.*, 1953, **29**,

543-544; 544-546. [Lab. Ricerche Vister, Casatenovo, Como.]

In normal rats injection of adenosinetriphosphate in graded doses reduced the ascorbic acid content of the adrenal glands.

In hypophysectomised rats the effect was the same with the smaller doses of adenosinetriphosphate, but with the highest, 20 mg. given intraperitoneally or 1 mg. given intravenously, there was no reduction. It is suggested that the large dose promoted synthesis of ascorbic acid and thereby masked the simultaneous fall.

MILKOVIĆ, S. Influence of vitamin C on preputial glands and thymus in intact and castrated-

N.A. and R., July 1954

adrenalectomised rats. *Arch. internat. Physiol.*, 1954, **62**, 1-5. [Med. Fac., Univ. Zagreb.]

Rats which had been castrated and had had their adrenal glands removed were given 50 mg. Na ascorbate in 4 daily doses at 5-hr. intervals and had a 0.5 per cent. solution of ascorbic acid in saline to drink; others received only saline. Corresponding groups of intact animals were treated similarly. The weight of the thymus glands in the adrenalectomised and castrated animals was significantly less in those given ascorbic acid than in those given saline only. Intact rats showed no difference. In none of the rats was there any significant effect of ascorbic acid on the weight of the preputial glands, expressed as mg. per 100 g. bodyweight.—W. Godden.

3143

OSTER, H. L., KRETCHMAR, A. L. and BETHELL, F. H. **Effect of whole body X-irradiation on ascorbic acid of rat tissues.** *Proc. Soc. Exp. Biol. Med.*, 1953, **84**, 470-473. [Atomic Energy Commission Biol. Effects Irradiation Lab., Univ. Michigan, Ann Arbor.]

The effect of exposing the whole body to X-rays was studied on 2 strains of rats. In the Long Evans strain exposure of the whole body to 710 r produced an immediate, significant decrease in the ascorbic acid content of the adrenal glands, muscle and blood and a less marked decrease in the thymus, liver and spleen (see Abst. 2559, Vol. 17). In rats of the Wistar strain exposure to 1000 r gave a decrease of ascorbic acid in the adrenal glands only; the content of the other organs tended to increase at first.—W. Godden.

BAMFORD, E. and FENTON, F. **Home-freezing vs. home-canning of peas. Palatability, ascorbic acid, total solids, and colour.** *J. Amer. Dietetic Assoc.*, 1953, **29**, 1221-1225. [New York State Coll. Home Econ., Cornell Univ., Ithaca.]

In palatability, quality, and ascorbic acid content, home-frozen peas were better than home-canned peas. In home freezing, preliminary steam blanching followed by partial vacuum cooling gave better results than water blanching. In home canning, cold-pack peas showed higher palatability and ascorbic acid retention than hot-pack peas. All the tests were made with one variety of peas.—W. Godden.

3148

HARDING, C. F. and DAVID, J. J. **The effect of certain mineral nutrients on the ascorbic acid content of leaf lettuce.** *Food Res.*, 1954, **19**, 138-145. [Macdonald Coll., McGill Univ., Que.]

Sand-culture experiments of factorial design were made with leaf lettuce during winter and spring in a greenhouse, the amounts of N, P and K supplied in the culture solution being varied one at a time. N was the only fertiliser element to produce a significant variation in the ascorbic acid content of the crop and this only in the winter experiment. In general the effect of increasing N and P was to increase the ascorbic acid content, but increase of K caused a decrease. The balance between the 3 fertiliser elements was as important as the amount of any one nutrient supplied.

The activity of glucose-6-phosphate and 6-phosphogluconate dehydrogenases in cell-free extracts of mammary glands of rats increased rapidly from the end of pregnancy to the end of lactation and then fell very low in the involuting gland. Similar, though less pronounced, changes were previously reported by Folley and Greenbaum (Abst. 1927, Vol. 17) for arginase and alkaline phosphatase.—W. Godden.

- HECK, W. and PELIKAHN, H. Über Magen-Proteinasen im Säuglings- und Kindesalter. [Stomach proteases in infants and children.] *Ztschr. Kinderheilk.*, 1953, **74**, 30-49. [Kinderklin., Univ. Göttingen.]

Pepsin, cathepsin and pH were estimated in the gastric juice of infants and children. In 72 healthy children the enzyme content per ml. gastric juice increased with age, the average values for cathepsin and pepsin, reckoned in μg . of tyrosine N, increasing from 10 in premature infants to 240 in schoolchildren, with a wide scatter within each age group. For infants with infectious or gastric disorders the values were lower than in healthy infants, but there was no simple relation between the clinical picture and the disturbance of enzyme production. Formation of pepsin seemed to be more sensitive to disturbing influences than that of cathepsin.

Practical measures suggested by these experiments are the administration of protein hydrolysates to premature infants in need of protein additional to that from human milk, and of commercial enzyme preparations to older infants with chronic gastric disorders.—M. B. Richards.

N.A. and B., July 1954

tryptic hydrolysis of casein *in vitro*. *Nature*, 1953, **172**, 1152-1153. [Nutrit. Res. Labs., Indian Counc. Med. Res., Coonoor, S. India.]

Total and essential amino-acids were estimated after digestion of casein by trypsin for 24 to 120 hr. with or without ovomucoid from duck's eggs. In its presence the release of amino-acids was inhibited; of individual acids, release of histidine, lysine, threonine and valine was most affected, that of isoleucine, leucine and tryptophan moderately and that of arginine, methionine, phenylalanine to no significant degree. A similar action *in vivo* may, it is suggested, account for the low nutritive value of duck's in comparison with hen's egg white (Dikshit and Patwardhan, *Current Sci.*, 1950, **19**, 18).—D. Harvey.

DEL COURT, A. A propos de l'activité estérasiqne et lipasique du sérum sanguin et du suc pancréatique. [Esterase and lipase activity of blood serum and pancreatic juice.] *Acta gastro-enterol. belg.*, 1953, **16**, 703-710. [Dept. Med., Univ. Chicago.] English summary.

With Seligman's technique, no pancreatic lipase was found in the serum of normal subjects or of 3 patients with acute pancreatitis. In the study of pancreatic disorders the value of this technique is limited to examination of duodenal juice collected after stimulation of the pancreas. The serum of dogs had lipolytic activity comparable with the lipase activity of the pancreatic juice. This lipase activity persisted, without appreciable modification, several months after removal of the pancreas, indicating that the lipase activity in the serum of the normal dog is not solely of pancreatic origin. The results were confirmed by electrophoretic studies.—M. B. Richards.

CACIOPPO, F., QUAGLIARIELLO, E., COLTORTI, M. and DELLA PIETRA, G. Fosfatasi alcalina e pH ottimo. [Alkaline phosphatase and optimum pH.] *Arch. Sci. biol., Bologna*, 1953, **37**, 563-573. [Ist. Chim., Fac. Med. Chirurg., Univ. Naples.]

In presence of Mg and with decreasing concentration of the substrate the optimum pH for alkaline phosphatase activity approached neutrality. With purified phosphatase in the absence of Mg and at substrate concentrations of 7.4, 14.8 and 37 μ g. per ml., the optimum pH was 9, but addition of

Mg shifted the optimum towards neutrality. With lower substrate concentrations of 5 and 3 μ g. per ml., even without addition of Mg, the optimum pH was lower, but addition of citrate caused a return to a more alkaline value. This probably indicated the presence of Mg in the enzyme extract, not completely removed in the process of purification. Such residual Mg might be sufficient to have an appreciable activity at low substrate concentrations.

It is considered that the shift of optimum pH of phosphatase activity towards neutrality when the substrate concentration is very low can be explained by the action of Mg^{++} on the enzyme.

M. B. Richards.

3159

FIŠER-HERMAN, M. and PERŠIČ, D. Prosječni nalazi alkalne fosfataze u serumu zdravih ljudi. [Average values for alkaline phosphatase in the serum of healthy human beings.] *Acta med. jugoslav.*, 1953, **7**, 261-264. [Inst. Clin. Chem., Fac. Pharm., Zagreb.] German summary.

Alkaline phosphatase was estimated in the blood serum of 105 healthy adults. The results expressed in Bodansky units and in King Armstrong units corresponded with those in the literature.

For a group of girls from 7 to 14 years old in a children's home some very high values were obtained; no clinical cause for these could be found. (From summary).—E. M. Hume.

3160

SUKUMARAN, M. and BLOOM, W. L. Influence of diet on serum alkaline phosphatase in rats and men. *Proc. Soc. Exp. Biol. Med.*, 1953, **84**, 631-634. [Dept. Med., Emory Univ., Ga.]

In young rats weighing about 175 g. the serum alkaline phosphatase after adrenal removal was somewhat higher than in normal adult rats. In both groups serum alkaline phosphatase was decreased by fasting for 24 hr. In fasted normal rats feeding with glucose or egg albumin did not restore phosphatase activity, but fat restored it almost to normal.

In hospital patients without liver or bone disorders serum alkaline phosphatase activity was much lower than in rats, but was also reduced by fasting for 20 hr. and restored by a high-fat meal, though not by carbohydrate or protein.

3162

ÖBRINK, K. J. **The mode of action of food as a gastric stimulant. A study with some quaternary ammonium derivatives.** *Acta physiol. scand.*, 1954, **30**, 282-288. [Inst. Physiol., Univ. Upsala.]

The effects were studied of 2 quaternary ammonium bases, Banthine and Vegolysin, on the secretion of gastric juice by Heidenhain pouches in dogs.

Neither substance inhibited secretion induced by injection of histamine. Banthine inhibited secretion after feeding. Vegolysin, but not Banthine, prevented secretion after injection of insulin.

These results indicate that Banthine inhibits food-induced secretion at some point before the release of histamine; therefore food does not produce secretion directly by liberating histamine. The failure of Vegolysin to prevent secretion after food means that neither the vagus nor synaptic transmission is concerned in producing a stimulating substance, and suggests that secretion after feeding is effected by the local nerve plexi of the stomach.—A. T. Phillipson.

3163

ÖBRINK, K. J. **Bonedust-meat mixture as a test meal for continuous gastric secretion.** *Acta physiol. scand.*, 1954, **30**, 275-281. [Inst. Physiol., Univ. Upsala.]

Bonedust, mixed with forcemeat almost free of fat and carbohydrates but containing 9 per cent. protein and protein derivatives and small amounts of keratin and fluorine, produced a greater increase in the quantity of gastric juice secreted by Heidenhain pouches in dogs than that produced by forcemeat alone. Most of the effect from the bonedust could be obtained from equivalent quantities of Ca triphosphate. Ca lactate, sodium triphosphate and Ca citrate produced little secretion, but sodium glycerophosphate, in which phosphate is attached to the glycerine molecule, had a marked effect.

It is concluded that the stimulating property of bonedust lies in its trivalent monohydrogen phosphate content.—A. T. Phillipson.

3164

AITKEN, M. A., SPRAY, G. H. and WALTERS, G. **Gastric pepsin and the excretion of uropepsinogen in anaemia.** *Clin. Sci.*, 1954, **13**, 119-126. [Nuffield Dept. Clin. Med., Oxford.]

In normal subjects and patients suffering from different types of anaemia, steatorrhoea or the results of total gastrectomy there was a linear relation between the concentration of HCl and of pepsin in the gastric juice after histamine and between the concentration of pepsin in the gastric juice and the amount of uropepsinogen excreted in the urine. In subjects with histamine-fast achlorhydria both gastric pepsin and uropepsinogen were reduced or absent.

The value of uropepsinogen estimation as a preliminary test for gastric secretory activity is discussed.—L. Wills.

Terap., Univ. Catania.]

One hundred samples of human gastric juice obtained after a fast of at least 12 hr. were analysed.

The only important inorganic anion is Cl, which is present partly as HCl and partly as neutral Cl, either as basic Cl in combination with Na, K or Ca, or as a small organic fraction or Cl residue. The samples of gastric juice were divided into 4 groups according to their acidity, ranging from those with no free HCl to those with more than 1.5 per cent. As the amount of free HCl increased, the concentration of basic Cl in the form of NaCl fell. The concentration of KCl remained almost constant and that of CaCl₂, which was present in small amounts, showed slight variations. The concentration of total Cl was relatively constant.

KAMBOKA, K., MORIMOTO, H., TAKAHASHI, S. and KUBOTA, D. [Studies on the digestion of ruminants. 1. On the change of nitrogen distribution and pH in the rumen content.] *Bull. Nat. Inst. Agric. Sci., Chiba, Japan* [G], 1953, No. 7, 169-174. In Japanese: English summary.

Two goats with rumen fistulae were fed on high-, medium- and low-protein diets and on a low-protein diet supplemented with urea. Samples

of rumen contents were examined at intervals for 24 hr. N content decreased with time, most rapidly after the high-protein diet. Bacterial and protozoal N together accounted for about half the total N in the rumen. Except for the sample taken 24 hr. after food, which showed a high pH, the pH of the rumen was from 5.4 to 6.6; the lowest value was obtained 4 hr. after food. (From summary.)—W. Godden.

3173

DAVIDSON, J. **A comparative study of the pigments in microbial fractions from the sheep's rumen and in the corresponding diet.** *J. Sci. Food Agric.*, 1954, **5**, 86-92. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Samples of rumen contents obtained by fistula from a sheep fed on chopped meadow hay were fractionated, after filtering through surgical gauze, by centrifuging at 500, 8000 and again at 8000 g. after adjusting the pH to 4, and the pigments were estimated in the fractions.

The pigmentation of the microbial fractions was caused by pigments usually associated with plant chloroplasts. Assessment of plant particle contamination of the microbial fractions from the amounts of the pigments present agreed in general with that obtained by a new direct count on a microscope slide. It was of the order of 10 per cent. Degradation of chlorophylls in the rumen was demonstrated and its extent was found to depend on the nature of the vegetable material in the diet.—W. Godden.

3174

MOIR, R. J., SOMERS, M., SHARMAN, G. and WARING, H. **Ruminant-like digestion in a marsupial.** *Nature*, 1954, **173**, 269-270. [Inst. Agric., Dept. Zool., Univ. W. Australia, Nedlands.]

The kangaroo is a true herbivore, and consequently can be expected to digest cellulose, and its alimentary morphology suggests that it is closer to the ruminant than to animals in which the large intestine is enlarged. The experiments reported were performed on *Setonix brachyurus*. Dissection showed that the stomach was sacculated in the upper regions and possessed a well-defined oesophageal groove. Microscopical examination of the stomach contents showed a rich microbial population similar to, but simpler than, that of the sheep's rumen. Microbial erosion of plant fragments was seen, and steam-volatile fatty acids, from 2 to 15 m.mol. per 100 ml., were present in the stomach contents. These acids were mostly absorbed by the time the digesta reached the fundus of the stomach. More volatile fatty acids were present in blood leaving the stomach and caecum than in peripheral blood. These acids were removed by the liver and tissues. The blood

sugar was low and, like the sheep, *Setonix* tolerated insulin hypoglycaemia well.

Setonix, in fact, is closely similar to the sheep in these respects. The similarity is interesting from an evolutionary point of view, as the marsupials and Eutheria are held to have been separate since the Cretaceous period.

Setonix weighs 2 to 3 kg. and promises to be a cheap laboratory animal in which metabolic problems similar to those of ruminants may be studied.—A. T. Phillipson.

PONZ, F. Inhibición de la absorción intestinal de glucosa por el ión cúprico. [Inhibition by the cupric ion of absorption of glucose from the intestine.] *Rev. española Fisiol.*, 1953, 9, 205-211. [Lab. Fisiol. Animal, Fac. Cien., Univ. Barcelona.] English summary.

The effect of the cupric ion on the intestinal absorption of glucose by the rat was studied by the Sols and Ponz technique with 4 successive absorptions, each of 30 min. A 5.4 per cent. solution of glucose was used, and CuSO_4 in different concentrations was present in the second and fourth absorptions of each series. From concentrations of 0.0001 *M* upwards, Cu^{++} inhibited absorption of glucose. With a concentration of 0.0002 *M* the inhibition was 10 to 30 per cent. in the first absorption, and about twice as great in the second absorption with Cu. With a concentration of 0.005 *M* inhibition was 40 to 80 and 80 to 100 per cent. with Cu. After Cu absorption thorough washing of the loop did not remove the inhibiting effect, which persisted in the next test with glucose alone. The inhibitory effect of Cu^{++} on the glucose absorption must be due to a local effect on the absorbent epithelium, and not to a general toxic effect, for the presence of Cu in a different intestinal loop, even in concentrations of 0.001 *M*, had no effect on the absorption of glucose

in the other loop. Inhibition is attributed to the fixation of Cu^{++} by ionic or —SH groups of the proteins of the mucosa.—M. B. Richards.

BYERS, S. O., FRIEDMAN, M. and GUNNING, B. Observations concerning the production and excretion of cholesterol in mammals. 11. The intestinal site of absorption and excretion of cholesterol. *Amer. J. Physiol.*, 1953, 175, 375-379. [Harold Brunn Inst., Mount Zion Hosp., San Francisco, Calif.]

The large intestines were removed from a group of rats, which were then given 3 ml. olive oil by stomach tube. After 72 hr. total stomach and intestinal contents were taken for estimation of total sterols, cholesterol and non-cholesterol sterols. The control group were treated similarly, but the faeces were pooled with the gut contents for analysis. The animals without large intestines excreted as much cholesterol and almost as much total sterol as did the intact rats, and it is suggested that the small intestine is the chief site of cholesterol excretion.

The absorption of endogenous cholesterol was studied by giving olive oil to rats and then removing their colons and collecting lymph from the thoracic ducts for 24 hr. Control animals had also thoracic duct cannulae. Lymph from the rats without colons contained only about half as much cholesterol as lymph from the controls, but the loss of a large part of the intestinal vascular bed may account for much of the difference.

The role of the small and large intestines in the absorption of exogenous cholesterol was studied in several ways. Cholesterol dissolved in olive oil was given by mouth to rats (1) with their large intestines removed and with thoracic duct cannulae, (2) with intact large intestines, but with diversion of the bile either to the ascending colon or to the stomach, or (3) with small portions of their large intestines removed 3, 6, 12 and 24 hr. after the cholesterol was given. These experiments showed that the cholesterol given by mouth was absorbed exclusively by the small intestine and that bile was necessary for absorption.

Rats with ligatures about the middle of their small intestines were given, either by mouth or into the distal portion of the small intestine at a point below the ligature, cholesterol dissolved in olive oil; cholesterol was estimated in thoracic lymph. These studies showed that the distal half of the

small intestine was the only portion capable of absorbing exogenous cholesterol.—G. A. Garton.

MOHAN SINGH, M., KAPOOR, S. P. and SINGH, G. **Normal haematological values in young Punjabi females.** *Indian Med. Gaz.*, 1953, **88**, 316-321. [Dept. Pathol., Med. Coll., Amritsar.]

Blood samples from 100 healthy women aged from 17 to 24 years, medical students and nurses from upper middle-class Punjabi families, gave the following mean values: Hb 13.09 ± 0.86 g. per 100 ml., total red cell count $4.55 \pm 0.04 \times 10^6$ per c.mm., packed cell volume 41.6 ± 2.7 per cent., mean corpuscular volume 92.23 ± 5.04 c. μ ., mean corpuscular Hb 29.04 ± 1.78 μ g., mean corpuscular Hb concentration 31.47 ± 0.51 per cent., total white cell count 7358, range 4000 to 10,700 per

c.mm. For serum proteins the means for 59 of the subjects were: total 7.20 ± 0.26 , albumin 5.05 ± 0.26 , globulin 2.19 ± 0.21 g. per 100 ml. For serum Ca the mean for 46 of the subjects was 10.75 ± 0.44 mg. per cent. Comparison with values quoted from the literature showed that the haematological values, though below those of other countries, were mostly higher than those from other parts of India.

The average diets were: medical students, milk $\frac{1}{4}$ to $\frac{1}{2}$ seer, chapattis 5 or 6, made from 3 chhataks wheat, vegetables $\frac{1}{4}$ seer, dhal $\frac{1}{2}$ chhatak, curd 2 chhataks, with moderate quantities of fruits in season, and tea, daily, 1 egg on alternate days and 2 oz. meat twice a week (cheese for vegetarians); nurses, milk $\frac{1}{4}$ seer, chapattis 4 or 5, made from 2 $\frac{1}{2}$ chhataks wheat, vegetables $\frac{1}{4}$ seer, dhal $\frac{1}{2}$ chhatak, meat 1 chhatak (1 oz. butter for vegetarians), small quantities of fruit, and tea, daily, with 1 egg on alternate days. [1 seer is about 2 lb., and 1 chhatak, 2 oz.]—W. M. Deans.

GOLDECK, H., REMY, D. and LABHARD, H. Eisenmangel und Schwangerschaft. [Iron deficiency and pregnancy.] *Deutsch. med. Wochenschr.*, 1954, **79**, 211-213. [2. Med. Klin., Univ. Hamburg, Eppendorf.]

Of 100 apparently normal pregnant women, mostly in the second half of pregnancy, 61 had Hb above 11 g. and serum Fe above 90 μ g. per 100 ml., values assumed to be the lower limits of normal; 5 had Hb between 10 and 11 and normal serum Fe; 12 had both low Hb and low serum Fe; and 22 had normal Hb but low serum Fe, and were considered to be in latent Fe deficiency. Serum Fe fell with increasing parity. Of the 61 in group 1, 18 were given 204 mg. Fe by mouth; serum Fe rose rapidly in all these and it is considered that they too were deficient in Fe. The 5 in group 2, on the other hand, showed the "pseudo-anaemia" due to the increased plasma volume. The conclusion is that Fe treatment during pregnancy is justifiable in a higher proportion of cases than is generally supposed.—W. M. Deans.

3188

GERRITSEN, T. and WALKER, A. R. P. **The effect of habitually high iron intake on certain blood**

values in pregnant Bantu women. *J. Clin. Invest.*, 1954, **33**, 23-26. [S. African Inst. Med. Res., Johannesburg.]

Estimations of Hb, haematocrit value, serum Fe and Fe-binding capacity were made for 48 non-pregnant and for 92 pregnant Bantu women, of whom 43 were less than 22 weeks and 49 were between 26 and 40 weeks pregnant. Analyses of samples of cooked or sour porridge and beer showed that their intake from these sources alone might be from 23 to 202 mg. Fe, mean 171 mg., daily. Contrary to expectation, Hb and haematocrit values did not fall in the second half of pregnancy. Data are not available for individual subjects throughout pregnancy, but it is thought that the high Fe intake may allow a quantitative increase in total Hb and total red cells which masks in the Bantu the fall considered physiological in white pregnant women.

In harmony with other reports, the total Fe-binding capacity was higher during the second than during the first half of pregnancy.

D. Harvey.

3189

HOLMES, E. G. Examination of the red-blood counts, haemoglobin, packed cell volume, serum iron and iron continuing [combining] capacity of the blood and serum of a small series of pregnant women at Mulago Hospital. *East African Med. J.*, 1953, **30**, 427-429. [Dept. Physiol., Makerere Coll.]

In 45 unselected pregnant African women of whom 16 were anaemic, blood examinations showed the usual fall in Hb, red blood cells and packed cell volume in the later months though the mean corpuscular volume, mean corpuscular Hb and mean corpuscular Hb concentration were within normal limits. As pregnancy proceeded the combined Fe in the serum decreased and the Fe-binding capacity increased.—L. Wills.

3190

RUSOFF, L. L., JOHNSTON, J. E. and BRANTON, C. Blood studies of breeding dairy bulls. 1. Haematocrit, hemoglobin, plasma calcium, plasma inorganic phosphorus, alkaline phosphatase values, erythrocyte count, and leucocyte count. *J. Dairy Sci.*, 1954, **37**, 30-36. [Dairy Dept., Louisiana Agric. Exp. Stat., Baton Rouge.]

Blood samples were obtained on 3 consecutive days each month for 1 year from 5 Jersey, 5 Guernsey and 5 Holstein breeding bulls under semi-tropical conditions. Each bull was housed alone and had access to 0.9 acre pasture. A grain ration was given at the rate of $\frac{1}{2}$ lb. per 100 lb. liveweight, and grass hay was given during periods of poor pasture.

Significant breed differences were found for packed red cell volume, alkaline phosphatase value and leucocyte count. Packed red cell volume, Hb value and leucocyte count rose and plasma alkaline phosphatase fell when the environmental temperature rose above 80° F.—J. N. Aitken.

3191

LAURELL, C. B. Isolation and properties of crystalline Fe-transferrin from pig's plasma. *Acta chem. scand.*, 1953, **7**, 1407-1412. [Lab. Clin. Chem., Univ. Lund.]

Techniques of preparation, purification and crystallisation are described. The product contained 16.3 g. N, 1.4 g. carbohydrate and between 0.120 and 0.136, mean 0.126, g. Fe per 100 g.; it was practically free from lipids. Its purity after recrystallisation was found to be measured better by the change which occurred in the ratio between absorption at 470 m μ . and 408 m μ . than by electrophoretic analysis.—D. Harvey.

3192

JELLIFFE, D. B. Serum proteins in the newborn African. *Doc. med. geogr.*, 1953, **5**, 286-288. [Univ. Coll. West Indies, Jamaica.]

The serum proteins were estimated in cord blood from 34 apparently full-term African babies, the children by normal delivery of normal women who were having a low-protein diet. The mean figures in g. per 100 ml. were for total protein 5.82 with range 4.80 to 7.30, albumin 3.84 with range 2.50 to 4.30, and globulin 2.15 with range 1.55 to 3.90. The figures are within the range reported for newborn Caucasian infants.—L. Wills.

3193

TOMAN, M. and KAZDOVÁ, D. Vliv jednotlivých druhů kojenecké potravy a bílkovinných přísadků na hladinu bílkovin v krvi nedonošenců. [The influence of foods and protein supplements upon the blood protein level in premature infants.] *Lékařské listy*, 1954, **9**, 42-44. [Pediat. Clin., Med. Fac., Masaryk Univ., Brno.] English, French and Russian summaries.

In 164 premature infants the blood protein level was estimated immediately after birth and subsequently before and after changes in diet or addition of protein hydrolysates. No significant increase of blood protein occurred. Sudden increase of the protein content of the diet produced a slight temporary rise in blood protein, but it fell in a short time to the initial level.

A. Jančařík (Czechoslovakia).

PAEZ PUMAR, H., E. Algunos aspectos de la protemia en embarazadas de la clase obrera de

N.A. and R., July 1954

Caracas. [Blood protein in pregnant women of the working class in Caracas.] *Arch. venezol. Nutricion*, 1952, **3**, 299-307. [Inst. Nac. Nutrición.] English and German summaries.

Of 250 pregnant women 61.13 per cent. had total serum protein values of less than 6 per cent. The average was 5.87, with extremes of 7.88 and 4.05. The average values for albumin and globulin were 3.28 and 2.58 per cent., and the albumin : globulin ratio was 1.30. No significant difference could be attributed to the month of pregnancy or to the presence of oedema, which occurred in 44.13 per cent. No relation was found between total protein and the values for red corpuscles and Hb. A number of the women received for from 1 to 3 months free meals which supplied more than 40 per cent. of the daily requirement for most of the nutrients, but no significant change in the blood protein occurred.—M. B. Richards.

TARANOV, M. T. Azotistyi profil' i aminokislотноyi sostav syvorotki krovi zhereby ot raznogo vozrasta. [Nitrogen and amino-acid content of the blood serum of foals of different ages.] *Konevodstvo*, 1953, No. 10, 9-14. [Kaf. Biol. Khim., Mosk. Zootech. Inst. Konevodstva.]

The effect of weaning time on the blood serum of foals was investigated. Foals were weaned at 3, 5, 6 and 7 months. Total N, protein N, N.P.N. and amino-N, and tyrosine, phenylalanine, tryptophan, glycine, arginine, cysteine and methionine were estimated in the blood serum before and 1 month after weaning. Weaning affected the protein composition of the blood both quantitatively and qualitatively. The N compounds in the blood of 3-, 5- and 7-month-old unweaned foals differed to a greater extent from those of weaned foals than those of 6-month-old weaned and unweaned foals from each other.—W. Hughes.

SPECTOR, W. G. Labelled glycine in the nephrotic syndrome. *Clin. Sci.*, 1954, **13**, 1-10. [Dept.

Morbid Anat., University Coll. Hosp. Med. Sch., London.]

Glycine labelled with ^{15}N was given by mouth to one healthy child and 3 with nephrosis. When the isotope concentrations in the plasma protein fractions were plotted against time, curves of characteristic shape were obtained for both albumin and globulins. The close similarity of the albumin curves from plasma and urine in the nephrotic children seemed to indicate that these proteins are formed at the same site. In severe nephrosis the plasma albumin curves differed from normal in that they reached a higher peak and had a steeper slope in both ascending and descending portions. The possible significance of the abnormal shape of these curves is discussed.

WALKER, A. R. P., ARVIDSSON, U. B. and POLITZER, W. M. The significance of low serum calcium values in the South African Bantu. *S. African Med. J.*, 1954, 28, 48-51. [S. African Inst. Med. Res., Johannesburg.]

Estimations of serum Ca in boys, 23 aged from 7 to 12 and 54 from 14 to 15 years, 48 adult men and 33 non-pregnant, 38 pregnant and 55 lactating women confirmed reports by other workers that the level is about one-tenth lower in Bantu than in white subjects.

During pregnancy Bantu women differed from white women in showing an increase, not a decrease, in comparison with non-pregnant women of the same race, which conforms with the absence of reports of osteomalacia among pregnant Bantu women. There was no correlation between the Ca contents of blood and milk of the same mother, and paediatricians' impressions from the general health and growth of Bantu babies were that their mothers' milk could be no poorer than that of white mothers.

Mineralisation of bone appeared to be no less and the incidence of fractures no greater than in other populations, and the repair of fractures was no slower among Bantu than among Europeans. The incidence of dental decay was generally less in Bantu than in white subjects.—D. Harvey.

GHOSE, C. Studies on metabolism of calcium, inorganic phosphorus and cholesterol in pre-eclamptic toxæmias of pregnancy. *Indian Med. Gaz.*, 1953, 88, 363-368. [Dept. Midwifery, Nilratan Sircar Med. Coll., Calcutta.]

In 32 women with pre-eclamptic toxæmia in the last trimester mean blood serum Ca was significantly lower and mean serum inorganic P and serum cholesterol ester were significantly higher than normal. The rise in free cholesterol was not significant.—F. C. Aitken.

3207

GHOSE, C. Studies on metabolism of calcium, inorganic phosphorus and cholesterol in pregnancy with helminthic infection in Indian women. *Indian Med. Gaz.*, 1953, 88, 440-447. [Dept. Midwifery, Nilratan Sircar Med. Coll., Calcutta.]

In 81 pregnant women with subclinical worm infestation and without clinical evidence of anaemia variations from normal in serum Ca, inorganic P and total cholesterol were not significant. Cholesterol ester values were significantly below normal.—F. C. Aitken.

3208

STURGEON, P. (with CHRISTIAN, E.) Studies of iron requirements in infants and children. 1. Normal values for serum iron, copper and free erythrocyte protoporphyrin. *Pediatrics*, 1954, 13, 107-125. [Child. Hosp., Los Angeles, Calif.] Spanish summary.

Specimens of blood were obtained from 237 infants and children; 24 were of cord blood, 48 were from infants aged 6 hr. to 12 days and 165 from children aged 2 weeks to 10 years. For comparison the blood of 34 men was studied.

Compared with the normal adult the newborn infant's serum Fe, serum Cu and free red cell protoporphyrin were high. At age 12 hr. serum Fe was low with little change in Cu and protoporphyrin. By 4 to 10 months the pattern characteristic of normal infancy was established: low serum Fe, 50 $\mu\text{g.}$ per 100 ml., high serum Cu, 146 $\mu\text{g.}$ per 100 ml., low saturation of total serum Fe-binding capacity, 12 per cent. and high free red cell protoporphyrin, 70 $\mu\text{g.}$ per 100 ml. In older children differences from adults were less pronounced. Extreme ranges in values were found in different subjects at most ages.

N.A. and R., July 1954

Data were obtained also for Hb, red cell count and packed red cell volume. Hb fell with serum Fe until at 4 months of age average Hb was 10.7 g. per 100 ml. After 4 months of age red cell count rose without an associated rise in Hb. Average values of Hb, red cell count, mean cell volume and mean corpuscular Hb concentration for children aged 3 to 10 years were 12.2 g., 4.6 millions, 86 c. μ . and 30 per cent., respectively.—F. C. Aitken.

Estimating the distribution of fluid and electrolytes in the body.] *Nord. Med.*, 1954, **51**, 364-367. [Seraphimerlasarett, Stockholm.] English summary.

The application of accepted techniques to study the distribution of water, Na and K in 9 healthy and 18 acromegalic subjects is described.

3216

BARTELHEIMER, H. and SCHWARTZKOPFF, W. Fraktionierte Gewebssaftuntersuchungen. 5. Vergleichende quantitative und elektrophoretische Eiweissbestimmungen bei Normo-, Hypo- und Hyperproteinämien. [Studies of fractionated tissue juice. 5. Comparative quantitative and electrophoretic estimations of protein in (patients with) normal, low and high blood protein.] *Ztschr. ges. exp. Med.*, 1953-1954, **122**, 478-496. [I. Med. Klin., Städt. Krankenhaus Moabit, Berlin.]

The intracellular fluid has a considerable content of protein. Its magnitude cannot be given exactly from the present investigations, but it is lower than that of fluid from cantharides blisters, and is not more than 50 or 60 per cent. of the protein content of serum. The percentage of albumin is often higher in tissue fluid than in serum.—M. B. Richards.

3217

DEMMLING, L., KINZLMEIER, H. and HENNING, N. Über die quantitative Zusammensetzung der

Organproteine. (Elektrophoretische Untersuchungen.) [The quantitative composition of the proteins of organs. (Electrophoretic studies.)] *Ztschr. ges. exp. Med.*, 1953-54, **122**, 416-430. [Med. Poliklin., Univ. Würzburg.]

Organs of rats were ground with sand, treated with 0.067 M phosphate buffer at pH 7.2, and either centrifuged or extracted for about 24 hr. at 3° C. The clear solution thus prepared for electrophoresis was mainly a salt-soluble tissue fluid extract. The organs examined included brain, heart and skeletal muscle, lung, liver, pancreas, gastric and intestinal mucosa, kidney, uterus, testis, smooth muscle and skin.

The 15 representative diagrams given show characteristic differences between organs. Compared with blood plasma, the organs other than the uterus and testis were relatively poor in albumin and rich in globulins. Brain substance was rich in α - and β -globulin, but the γ -component was small, as it was also in uterus and testis. In pancreas and striped muscle the chief component was γ -globulin; smooth muscle showed a more regular globulin distribution.—M. B. Richards.

3218

GARKAVI, P. G. Ob uchastii karnitina v nekotorykh biokhimicheskikh protsessakh i ego soderzhanii v mishtsakh razlichnykh zhivotnykh. [The participation of carnitine in some biochemical processes and its content in the muscles of different animals.] *Biokhimiya*, 1953, **18**, 302-304. [Lab. Biokhim., Akad. Med. Nauk. SSSR, Moscow.]

Carnosine and glycocyamine were not methylated by liver slices from rats when carnitine was used as the methyl source. Carnitine did not affect P metabolism in pigeon muscle, or muscular respiration. The carnitine contents of the muscles of several species, expressed as mg. per 100 g., were: cow 260, rat 57, red and white chicken muscles 124 and 48, pigeon 58, crow 73, frog 52 and carp 76.—W. Hughes.

3219

POLYAKOVA, N. M. Izuchenie sterinov golovno mozga khromatograficheskimi metodami. [A chromatographic study of brain sterols.] *Dokl. Akad. Nauk S.S.S.R.*, 1953, **93**, 321-324. [Inst. Biokhim., Akad. Nauk. Ukrain. SSSR.]

The white and grey matter of human cerebral hemispheres contained 14.0 and 8.0 per cent., respectively, of unsaponifiable substances, on a dry matter basis. Sterols, mainly cholesterol and its isomers, amounted to 90 per cent. of the unsaponifiable material from the white and 85 per cent. of that from the grey matter. Three compounds of low melting-point which gave negative tests for sterols were isolated but not identified.

Unsaponifiable material from grey but not from white matter was shown to contain 7-hydroxycholesterol.—W. Hughes.

3220

SHABANOVA, I. A. Osobennosti sostava i uglevodnofosfornogo obmena myshts kryss pri eksperimentalnoi myshechnoi distrofii. [Composition and phosphate metabolism of rat muscle in experimental muscular dystrophy.] *Biokhimiya*, 1953, **18**, 385-392. [Lab. Biokhim., Akad. Med. Nauk. SSSR, Moscow.]

Muscular dystrophy was produced in rats by depriving them of vitamin E; they were killed and their thigh muscles were compared with those of normal rats. Dystrophic muscle contained 30 per cent. less total P and almost the same amount of inorganic P as normal muscle. The chief decrease was in easily hydrolysable P, including the adenosinephosphoric acids. Free adenylic acid was almost unchanged. Creatine, carnosine and anserine fell, particularly anserine, which decreased by 73 per cent. Amino-N and also N in unidentified compounds increased.

Oxidation of phosphoglyceryl aldehyde, linked with phosphorylation, broke down. The accelerating effect of carnosine on the linking of inorganic phosphate and the formation of phosphoglyceric acid, which occurs in healthy animals, was not observed in rats suffering from muscular dystrophy. W. Hughes.

WEINGES, K. F., LEPPELMANN, H. J. and HARTL, F. Über den Calcium-, Phosphat- und Carbonatgehalt menschlicher Skeletteile im Zusammenhang mit Fragen der Knochenstruktur und ihres Umbaues unter normalen und krankhaften Bedingungen. Vorläufige Mitteilung. [The calcium phosphate and carbonate content of parts of the human skeleton in relation to their structure and metabolism in health and disease. Preliminary communication.] *Klin. Wochenschr.*, 1953, **31**, 1057-1059. [Pathol. Inst., Univ. Munich.]

Sp. gr. was estimated and analyses were made of bone from the roof of the skull and from the

collarbone of 50 male and 50 female bodies of all ages. The mean percentage composition of the roof of the skull and collarbone, respectively, was Ca 31 and 29.5, PO_4 54 and 52.5, and CO_3 7.5 and 7. The higher the sp. gr. and the denser the structure, the lower was the content of Ca, CO_3 and PO_4 . Analysed according to age and sex, the values showed that with age the Ca and CO_3 content of the bone increased, especially in females, with relatively low sp. gr. In chronic heart weakness with cyanosis, the CO_3 content of the bone tended to be high. In pregnancy, values for Ca and P were low, with high sp. gr.

E. M. Hume.

3224

EDELMAN, I. S., JAMES, A. H., BADEN, H. and MOORE, F. D. **Electrolyte composition of bone and the penetration of radiosodium and deuterium oxide into dog and human bone.** *J. Clin. Invest.*, 1954, **33**, 122-131. [Lab. Surg. Res., Peter Bent Brigham Hosp., Boston, Mass.]

Bone samples were obtained from 5 human subjects at post-mortem examination and from dogs under anaesthesia or within an hour after death. There was a close similarity in chemical composition of dog and human bone as expressed on a fat-free dry weight basis. Cortical samples contained from 13 to 22 per cent. water, cancellous bone from 32 to 52 per cent. The mean Na content of the human samples was 234 m. equiv. per kg. fat-free solids, with a range of from 215 to 273. In dog bones the mean was 229 m. equiv. per kg., range from 216 to 239. In all the samples, regardless of species or site, the Ca content was similar, with a mean of 12,000 m. equiv. per kg. fat-free solids.

Seven dogs and one man received intravenous injections of ^{24}Na and samples of blood and bone were taken from 2 to 50 hr. later from the dogs and 26 hr. later from the man. About 45 per cent. of the bone Na in the dogs was exchangeable in the first 4 hr. and there was little change during the next 20 hr. In the human subject the exchangeable Na was 35 per cent.

A more extended study was made on 3 dogs by means of serial bone and blood biopsies during a month after injection of ^{22}Na , while the dogs received a low-Na diet. These results also indicated that about 45 per cent. of the bone Na was readily exchangeable and that the rest showed no tendency to exchange even under conditions of Na depletion.

In 4 dogs injection of D_2O indicated that bone water was completely exchanged with serum water within 4 hr.

The distribution of sodium and water in the body and the study of changes in it are discussed.

BERGSTROM, W. H. (with BELL, E. H.) **The relationship of sodium and potassium to carbonate in bone.** *J. Biol. Chem.*, 1954, **206**, 711-715. [Dept. Paediat., Med. Coll. State Univ. New York, Syracuse.]

Data are presented for Na, K, Ca and CO_3 contents of fresh bone from young and adult normal and adult acidotic rats; the ratios CO_3 :Ca, CO_3 :Na + K and Na + K:Ca are also given. Na and carbonate increased with age both absolutely and relatively to Ca. The ratio Na + K:Ca decreased in acidosis, and CO_3 :Na + K increased.

It is suggested that all the Na and K present in bone could be accounted for by the existence of combinations such as $\text{Ca}-\text{O}-\text{CO}_2-\text{Na}$.

No difference was found between the protein from the healthy dentine from carious teeth and normal dentine, but there were differences between enamel protein from the healthy portion of carious teeth and from normal teeth. The amino-acids showing greatest changes were methionine, tryptophan, threonine, alanine, tyrosine, leucine and hydroxyproline.—D. Harvey.

3228

STACK, M. V. **The organic content of "chalky" enamel.** *Brit. Dent. J.*, 1954, **96**, 73-76. [Dept. Dent. Med., Guy's Hosp., London.]

From analyses of material from 2 sound teeth it was shown that enamel from 5 areas of the same tooth did not differ in content of organic matter; the ranges for the teeth were from 0.47 to 0.52 and from 0.56 to 0.59 per cent. of the air-dried material.

In samples of chalky enamel from the outer surfaces of 10 teeth the amount was greater, the mean being 1.48 per cent. The ratio of the contents of organic matter of chalky and normal enamel from each tooth was calculated; the range was 3.1 to 3.8 and the mean ratio 3.3. In similar

chalky enamel collected from inner surfaces overhanging major cavities in 10 other teeth the content of organic matter was greater than in samples from outer surfaces; the range was 4.4 to 7.5, mean 5.5 per cent.—D. Harvey.

The effect of moderate muscular effort on the adrenals of guineapigs was compared with that produced by the severe strain of starvation. In animals trained to swim for $1\frac{1}{2}$ hr. daily in water at body temperature there was no increase in heart weight, but the weight of the adrenals relative to bodyweight increased by 40 per cent. after 6 days and 65 per cent. after 15 or 16 weeks. No significant change occurred in the adrenal content of neutral fats and cholesterol and the only histological change was a slight increase in mitosis. Thus the reaction of the adrenals to a

slight chronic stress was purely quantitative, in the sense of a hyperplasia.

Starvation for 4 or 6 days caused little change in the weight of the adrenals relative to the original bodyweight, but considerable qualitative changes in the adrenal cortex, the "progressive transformation" of Tonutti, or the "alarm reaction" of Selye.—M. B. Richards.

PICKERING, D. E., FISHER, D. A., SCOTT, K. G., VAN WAGENEN, G. and SMYTH, F. S. **Growth and metabolism in normal and thyroid-ablated infant rhesus monkeys (*Macaca mulatta*).** 6. **Iodine metabolism in normal and thyroid-ablated infant rhesus monkeys (*Macaca mulatta*).** *Amer. J. Dis. Child.*, 1953, **86**, 574-586. [Dept. Paediat., Sch. Med., Univ. California.]

For earlier papers in the series see Abst. 643 and 1972, Vol. 24.

The iodine metabolism of 6 euthyroid and 4 athyroid immature rhesus monkeys was studied. The uptake of ^{131}I by the thyroids of the normal animals decreased with age. When from 5 to 15 μC . carrier-free ^{131}I was injected intraperitoneally it accumulated in the thyroid or was excreted by the kidneys. In the normal infant monkeys the uptake by the thyroid was considerable; radioactivity counts over the thyroid area in the athyroid monkeys were the same as those over the thigh. The uptake of ^{131}I by the thyroid was almost completely suppressed by an intravenous dose of 250 μg . L-thyroxine per kg. bodyweight, but this effect disappeared in 10 days. It was accompanied by an increased concentration of butyl-extractable I in the serum. Concurrent administration of thyrotropic hormone prevented this suppression of ^{131}I uptake by the thyroid. The rate of disappearance of labelled thyroxine from the plasma was similar in one euthyroid and one athyroid monkey.

Preparation of ^{131}I -labelled thyroxine is described.—B. W. Simpson.

3238

MAQSOOD, M. **Some aspects of thyroid physiology in the male.** *Zootechnia*, 1953, **2**, 258-273; 323-341. [Animal Res. Stat., Univ. Cambridge.] Spanish and French summaries.

The thyroid weight and rate of secretion of thyroxine of male rabbits decreased in relation to bodyweight with advancing age. The relation between thyroid weight and bodyweight is expressed by the equation

$$Y \text{ (thyroid weight in mg.)} = 0.527 x^{0.74} \text{ (} x = \text{bodyweight in g.)}$$

and that between rate of secretion of thyroxine and bodyweight by the equation

$$Y \text{ (} \mu\text{g. l-thyroxine secreted by a rabbit daily)} = 0.43 x^{0.48} \text{ (} x = \text{bodyweight in g.)}$$

In 16-week-old male rabbits there was a significant fall in thyroid weight and in thyroxine secretion during the summer months. Castration at the age of 8 weeks reduced thyroid weight and secretion at 32 weeks, but not at 12 weeks.

Thiouracil formed 0.1 per cent. of the ration except when the rabbits were less than 4 weeks old. Thyroxine was injected. When thyroprotein with an activity equivalent to 0.75 per cent. L-thyroxine was given to 4-week-old male rabbits as 0.06 or 0.1 per cent. of the ration for 12 weeks during the summer there was marked loss of bodyweight and mortality was high. When thyroprotein was given at the same levels in winter, growth was less retarded. When thyroprotein was given at 0.006 per cent., bodyweight increased. Administration of thyroxine below the estimated level of endo-

genous thyroxine secretion had no great effect on growth, but thyroxine given at from 30 to 50 per cent. above the normal secretion rate in 4-week-old rabbits for 4 weeks resulted in an increase of bodyweight. Advancing age reduced the rate of natural secretion, and if the dose of exogenous thyroxine was not reduced in proportion, growth was retarded.

It is suggested that seasonal variations and age should be taken into account when thyroid material is given to stimulate growth.—B. W. Simpson.

HALMI, N. S. **Regulation of the rat thyroid in short-term iodine deficiency.** *Endocrinology*, 1954, **54**, 216-224. [Dept. Anat., State Univ. Iowa, Iowa City.]

Groups of intact and hypophysectomised adult male rats received for about 20 days either a low-iodine diet (Remington) or a high-iodine diet (Rockland pellets). One group of hypophysectomised rats received daily subcutaneous injections of thyrotropic hormone (TSH). All the rats were given a tracer dose of carrier-free radio-active I and were killed 1 or 1½ hr. later. Thyroids were weighed, acinar cell heights were measured and the ratio of thyroid I in mg. per 100 g. thyroid to mg. I in 100 ml. serum was estimated. The pituitaries were also examined histologically.

There was no morphological change in the thyroids attributable to diet, but hypophysectomy reduced their size. In all groups the low-iodine diet increased the capacity of the thyroid for taking up iodide, but the increase was least after hypophysectomy, though TSH restored it to the level seen in intact rats.—B. W. Simpson.

3241

CALESNICK, B., HARRIS, W. D. and JONES, R. S. **Antithyroid action of antibiotics.** *Science*, 1954, **119**, 128-129. [Dept. Pharmacol., Hahnemann Med. Coll., Philadelphia, Pa.]

The effect on the thyroid gland of penicillin and aureomycin was compared with that of iodothiouracil and propylthiouracil. Five groups of 4 young white rats on stock diet of Pratt's Nurishmix with 1 per cent. iodised salt were given for 42 days potassium penicillin G or aureomycin at a level of 1 mg. per kg. food, or iodothiouracil (Itrumi) or propylthiouracil at 2 per cent.; 48 hr. before they

were killed 20 μC . ^{131}I was injected intravenously into each rat.

All the experimental groups showed larger thyroids and lower ^{131}I concentration than controls, but the antibiotics had less antithyroid effect than the thiouracils. Iodothiouracil produced far less vascularity than propylthiouracil.

CARE, A. D. **Goitrogenic properties of linseed.** *Nature*, 1954, **173**, 172-173. [Canterbury Agric. Coll., Lincoln.]

Ewes fed on a diet of linseed meal, oats and alfalfa hay produced lambs with large goitres unless KI or thyroxine was added to the drinking water. Groups of mice were given a balanced control ration, and the same ration with 50 per cent. crushed linseed meal and with and without KI, or with aqueous KCN or thiocyanate. One μC . radio-active iodine was injected intraperitoneally into animals from each group and the uptake curves obtained from the thyroids showed that supplementary KI prevented goitre and that the goitrogen in the linseed was thiocyanate. A similar investigation is being made with white clovers.

B. W. Simpson.

3244

TALMAGE, R. V., LOTZ, W. E. and COMAR, C. L. **Action of parathyroid extract on bone phosphorus and calcium in the rat.** *Proc. Soc. Exp. Biol. Med.*, 1953, **84**, 578-582. [U. T.-A.E.C. Agric. Res. Program, Oak Ridge, Tenn.]

Mature male rats were given subcutaneous injections of ^{32}P or ^{45}Ca , followed after 2 hr. by parathyroid extract, and were killed 10 hr. later. In other experiments parathyroid extract was given 24 hr. after the radio-active element and the animals were killed after another 24 or 48 hr.

The excretion of phosphate increased enormously after parathyroid extract; serum phosphate decreased at first, but later increased and finally exceeded the normal. Excretion of Ca increased less than that of P. The loss of radio-active P from the skeleton was much greater than that of Ca.

The action of the parathyroid hormone is discussed in the light of these results.—R. Hill.

JACOBS, E. **Sur le mécanisme d'action de la parathormone : effet du maintien d'un état d'hyperphosphorémie sur l'action hypercalcémiant de l'hormone.** [The mechanism of action of parathormone : the effect of main-

tenance of a high level of phosphorus in the blood on the power of the hormone to raise blood calcium.] *Arch. internat. Pharmacodyn.*, 1953, **95**, 225-233. [Lab. Méd. Exp., Univ. Brussels.] English summary.

The subjects were 7 bitches weighing between 20 and 25 kg. After a fast of 16 hr. a blood sample was taken and from 10 to 30 ml. of a solution containing 9.85 g. $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$ and 0.75 g. KH_2PO_4 per 100 ml. was given by stomach tube. From 20 to 30 min. later parathyroid extract was injected, partly intravenously and partly into muscle. Blood samples were taken at intervals and were usually followed by another dose of phosphate solution; the total amount of phosphate solution given ranged from 25 to 100 ml.

By the repeated administration of phosphate a drop in serum P was prevented in 7 out of 9 experiments. In 2 of these 7 there was no effect of the parathyroid hormone on serum Ca, but in the other 5 serum Ca rose. In the last 2 experiments there was a slight fall in blood P and a rise in blood Ca.

The significance of the results is discussed. An extra-renal mechanism is thought to control the rise in serum Ca after administration of parathyroid hormone.—D. Duncan.

KINSELL, L. W., MARGEN, S., PARTRIDGE, J. W., MICHAELS, G. D., BALCH, H. E. and JAHN, J. P. (with BILISOLY, J., COELHO, M., KIPP, E. and OLSON, F.) **Metabolic effects of "pituitary growth hormone preparations" in human subjects : summary of quantitative studies extending over a five-year period.** *J. Clin. Endocrinol.*, 1954, **14**, 110-117. [Inst. Metabol. Res., Highland Alameda County Hosp., Oakland, Calif.]

Pituitary growth hormone preparations were without consistent metabolic effect when administered to 3 normal men, a patient with panhypopituitarism, 2 with *retinitis pigmentosa* and 1 with rheumatoid arthritis. In a patient with myxoedema and no endogenous thyroid function 2 such preparations each gave significant retention of N, K and P, with some "rebound" when the preparation was withdrawn. No Na was retained; weight increased during treatment and was lost during "rebound".

The purity of the preparations is questioned, and contamination with thyrotropic hormone is suggested to account for the lack of anabolic effect in most subjects.—D. Duncan.

3249

STAMLER, J., PICK, R. and KATZ, L. N. **Prevention of coronary atherosclerosis by estrogen-androgen administration in the cholesterol-fed chick.** *Circulation Res.*, 1953, **1**, 94-98. [Cardiovascular Dept., Med. Res. Inst., Michael Reese Hosp., Chicago, Ill.]

The results confirm earlier findings (Pick *et al.*, *Circulation*, 1951, **6**, 276) that oestrogens are highly effective both prophylactically and therapeutically against cholesterol-induced coronary arteriosclerosis in cockerels. Combined administration of oestrogen and androgen, preventing oestrogen feminisation, was at least as effective as oestrogen alone. Neither androgen nor chorionic gonadotropin significantly affected cholesterol-induced coronary or aortic arteriosclerosis in cockerels.

KERPEL-FRONIUS, Ö., VARGA, F., KUN, K. and VÖNÖCZKY, J. **The relationship between circulation and kidney function in infantile dehydration and malnutrition.** *Acta med. hung.*, 1954, **5**, 27-45. [Dept. Paediat., Univ. Pécs, Hungary.] Russian summary.

Kidney function, cardiac output and oxygen consumption were studied in normal infants, in some showing acute dehydration after gastroenteritis, or simple wasting uncomplicated by infection, or athrepsia, and in others in whom pneumonia appeared along with malnutrition. Methods were as described by the authors in *Ann. paediat.*, 1951, **176**, 11 and *Acta paediat.*, 1951, **40**, 10.

In acute dehydration kidney function was much reduced and cardiac output was decreased but oxygen consumption was not diminished, with the result that the stagnating type of anoxia characteristic of acute circulatory shock appeared. In uncomplicated severe malnutrition kidney function remained normal, cardiac output and oxygen consumption were moderately reduced and anoxia seldom occurred. In athrepsia reduction of cardiac output was in most cases severe and anoxia did occur. When pneumonia was a complication inulin clearance rose, that of *p*-aminohippuric acid remained unchanged, cardiac output increased and oxygen consumption was below normal; in these circumstances the oxygen saturation of cerebral venous blood was well maintained.—D. Harvey.

3251

MCCANCE, R. A. and STRANGEWAYS, W. M. B. **Protein katabolism and oxygen consumption during starvation in infants, young adults and old men.** *Brit. J. Nutrition*, 1954, **8**, 21-32. [Med. Res. Coun. Dept. Exp. Med., Univ. Cambridge.]

The basal metabolism of 6 newborn male infants was measured for the first 48 hr. of life; no food was given and water intake was restricted. N breakdown during this period was also measured. The results were compared with those for young men aged from 21 to 30 and old men aged from 74 to 84 years, for the last 2 days of a 3-day starvation period.

Average figures for B.M.R. were 50, 26 and 21 Cal. per kg. in 24 hr., for body N breakdown 0.075, 0.17 and 0.12 g. per kg. in 24 hr., and for the proportion of energy derived from protein 4, 18 and 17 per cent., for the infants, young men and old men, respectively.—C. Warner.

3252

WEDGWOOD, R. J., BASS, D. E., KLIMAS, J. A., KLEEMAN, C. R. and QUINN, M. **Relationship of body composition to basal metabolic rate in normal man.** *J. Appl. Physiol.*, 1953, **6**, 317-334. [Natick QM Res. Development Lab., Lawrence, Mass.]

The bodyweight, height, surface area (SA) and B.M.R. of 17 young male adults were estimated, also the antipyrine, thiocyanate and T 1824 spaces,

from which were derived the total body water, intracellular (ICF), extracellular (ECF) and interstitial (ISF) water and plasma volume (PV) in litres.

Total body water being held constant, ICF and ECF were inversely related. The relation of the B.M.R. to the other variables was analysed in detail, and a multiple regression equation was derived:

B.M.R. (Cal. per hr.) =

$$14.13 + 3.79(\text{ISF}) + 0.787(\text{ICF}) - 0.075(\text{PV}) - 4.55(\text{SA}) \pm 3.22.$$

Of the total variation in B.M.R. 65 per cent. was accounted for by this equation. The results are discussed.—S. D. Morrison.

3253

TALAAT, M., HABIB, Y. A. and EL-KHANAGRY, H. **Studies on the basal metabolic rate of normal Egyptians.** *Acta med. scand.*, 1953, **147**, 221-226. [Dept. Physiol., Fac. Med., Alexandria.]

Estimations of B.M.R. were made on normal adults, 63 males and 53 females. All the latter were below the age of menopause, and the estimations were made between the 4th and the 10th post-menstrual day. The mean B.M.R. for males and females was, respectively, 39.86 and 36.99 Cal. per sq.m. per hr. These values do not differ significantly from the modified DuBois standards.

S. D. Morrison.

MURATA, S. [Studies on the basal metabolism of the Japanese. 4. On the basal metabolism of 17-years-old female. 5. On the basal metabolism of 18-years-old female. 10. On the basal metabolism of 13-years-old female. 11. On the variation of basal metabolism in relation to the onset of menstruation.] *Shikoku Acta Med.*, 1953, **4**, No. 2, 12-19; 20-24; No. 6, 22-25; 26-30. [Dept. Hyg., Sch. Med., Univ. Tokushima.] In Japanese: English summary.

4. For 120 girls aged between 17 and 18 years the averages were for respiration rate 18.1 and pulse rate 66.1 per min., R.Q. 0.93, and basal heat production 35.38 Cal. per sq.m. per hr. Mean weight was 49.15 kg. and mean height 151.2 cm.

5. For 93 girls between 18 and 19 years of age corresponding values were 17.0 and 65.7, 0.93, 34.72, 49.62 and 151.68.

Data are tabulated in full for each series.

10. For 81 girls aged between 13 and 14 years the averages were for respiration rate 18.8 and pulse rate 80.8 per min., R.Q. 0.92 and basal heat production 42.77 Cal. per sq.m. per hr. Mean weight was 38.05 kg. and mean height 144.5 cm.

Data are tabulated in full.

11. Metabolic rates were studied in 97 girls

aged 13 years of whom 30 had and 67 had not reached menarche. For the 2 groups the mean values were for weight 42.34 and 36.18 kg. and for height 147.4 and 144.3 cm., respectively. Corresponding values for the other characters for which differences between the groups were found were, body temperature 98.24° and 98.37° F., respiration rate 18.61 and 18.99 per min., pulse rate 78.5 and 81.3 per min., B.M.R. 41.52 and 43.85 Cal. per sq. m. per hr. (From summary.)—D. Harvey.

YOSHIMURA, H., INQUE, G., YAMAMOTO, M., YAMAJI, R., TANIMURA, Y., OOHARA, S., TAKAOKA, W., KOISHI, H., FUNAKI, H. and HAYASHI, M. **A contribution to the knowledge of dehydration of human body; some remarks on physiological effects of prolonged complete starvation.** *J. Biochem., Tokyo*, 1953, **40**, 361-375. [Inst. Physiol., Kyoto Prefectural Med. Coll.]

A Buddhist bishop, Soken Enami, aged 46, abstained completely from food and water for 8 days for religious reasons. He permitted the authors to study his metabolism. He lay on his bed and rose from time to time to pray; his prayers lasted about 1½ hr. daily. Mental and physical tranquillity were indispensable for enduring the abstinence.

Studies were made of the metabolism of energy, water, protein, Na, K, Cl and acid-base balance, of the physiology of respiration, circulation, temperature, regulation and renal excretion, and of the properties of blood and urine related to them. The findings are fully set out in tables and graphs.

The B.M.R. and body temperature were slightly raised. About 23 per cent. of the total body water, amounting to about 8 litres, was lost, of which about half represented insensible water loss, though the rate of loss of the latter was only about half the normal. More than half of the lost water was supplemented in the body by liberation of intracellular water which was mainly associated with nutrients. The circulating blood volume was reduced by about 16 per cent., but contraction of the blood vessels, especially in the limbs, afforded compensation. When exercise was taken the circulation and respiration were forced to accelerate, and the heart was then threatened with exhaustion in its effort to overcome the circulatory disturbances caused by blood concentration. Such acute heart exhaustion is presumed to be the cause of death in dehydration.—E. M. Hume.

ÅSTRAND, P. O. **A study of capacity for hard muscular work of 17 to 19-year-old male youths.** *Arbeitsphysiologie*, 1953, **15**, 251-254. [Dept. Physiol., Central Gymnastic Inst., Stockholm.]

Using the technique previously reported (Åstrand, "Experimental studies of physical working capacity in relation to sex and age," Munksgaard, Copenhagen, 1952) 34 well trained young men, 17 to 19 years of age, were set to run on a treadmill at 1° uphill at different speeds up to their maximum for from 6 to 8 min. The average maximum oxygen intake per kg. bodyweight was 59.2 ml. per min. for the 17-year-olds, 61.6 for the 18-year-olds and 61.3 for the 19-year-olds. The corresponding blood lactic acid values were 111, 107 and 101 mg. per 100 ml. At speeds of 8 and 12 km. per hr., the youngest group attained a heart rate 10 to 15 beats faster than that of the 19-year-olds and their lactic acid values were about 14 mg. per 100 ml. higher. If the 19-year-old youths are regarded as full grown, the 17-year-olds should be regarded as juniors with respect to their capacity for hard muscular work demanding endurance.

PHILLIPS, P. G. **The metabolic cost of common West African agricultural activities.** *J. Trop. Med. Hyg.*, 1954, **57**, 12-20. [Colonial Med. Res. Committee's Lab. Hot Climate Physiol., Oshodi, nr. Lagos, Nigeria.]

The activities for which 7 Nigerians provided data were sitting, standing, walking and stool stepping and others of an agricultural or industrial character, i.e., grass cutting, bush clearing, head panning, log carrying, tree felling and sawing. The open method of measurement was used and, where possible, the Douglas bag was wheeled on a trolley instead of being carried. All observations were made 2 hr. after breakfast.

Analyses of sample diets are tabulated; energy intakes were generally in excess of 2750 Cal., of which about 10, 24 and 66 per cent., respectively, were from protein, fat and carbohydrate.

The mean metabolic cost of sitting or standing was 51 Cal., and for stool stepping 12 or 24 times per min. it was 120 or 202 Cal. per sq.m. per hr. Compared with British sailors, reported on by Dunham *et al.* (*Med. Res. Council Report to Royal Naval Personnel Research Committee*, London, 1946) these Africans could be regarded as being more efficient at stool stepping. Walking at 3 m.p.h. required 120 Cal. per sq.m. per hr., a somewhat lower metabolic rate than that reported for Europeans, but when differences in clothing and in the weight of equipment carried are considered, the rate may not be significantly lower.

The means for other activities, in Cal. per sq.

Vol. 24, No. 3

m. per hr., were: log carrying with 20-kg. load 138; head panning with 20-kg. load 142 and with 30 kg. 173; grass cutting 177; hoeing 178; head panning with 35-kg. load 206; sawing 237; bush clearing 245; tree felling 332. In carrying a head load there was an increase in mean oxygen consumption which was linear with weights up to about 20 kg., but when these went up to 35 kg. there was a disproportionate increase in energy cost. Practices in Nigeria are in general agreement with these findings since, for long distances, porters' loads are normally about 14 kg. and rarely exceed 23 kg., but for short distances, as in the tin mines, they may exceed 27 kg.

The findings cannot be taken as confirmatory of the conclusions by U.S. workers (Robinson *et al.*, *Human Biol.*, 1941, **13**, 139) that the negroid is physiologically more efficient than the white subject.—D. Harvey.

EGLI, R., GRANDJEAN, E. and TURRIAN, H. **Arbeitsphysiologische Untersuchungen an Hackgeräten.** [Studies of physiology of work with hoeing tools.] *Arbeitsphysiologie*, 1953, **15**, 231-234. [Inst. Hyg., Tech. Hochsch., Zürich.]

By methods previously reported (Abst. 1839, Vol. 23) the energy output by 5 trained school-children was compared when using 3 types of hoe to loosen light and hard soils. On light soil for a given energy output twice as much ground could be covered with a circular hoe as with a hacking hoe. On heavy soil the circular hoe was still the most efficient but the differences between the 3 types were small.—W. Godden.

SCHOLZ, G. **Die Beziehung zwischen Schrittlänge und Schrittzahl beim natürlichen Gang.** [Relation between length of step and frequency of step in natural walking.] *Arbeitsphysiologie*, 1953, **15**, 211-222. [Inst. Verkehrswirtschaft., Tech. Hochsch., Hanover.]

One subject, 23 years old, walked without a load along a level 100 m. cinder track at different speeds and with different lengths and frequencies of step. Within the limits of 30 to 120 m. or 65 to 138 steps per min., speed, frequency and length of step were interdependent; there was a hyperbolic relation between speed and frequency. In natural walking there was a tendency to adjust frequency and length of step so that energy expenditure was at a minimum.—W. Godden.

RYHMING, I. **A modified Harvard step test for the evaluation of physical fitness.** *Arbeitsphysiologie*, 1953, **15**, 235-250. [Dept. Physiol., Central Gymnastic Inst., Stockholm.]

A step test, in which the Harvard test (Abst. 3517, Vol. 14) was modified by adopting platforms 40 cm. high for young men, 27 cm. for older men and 33 cm. for young women, all making 22.5 steps per min., was compared with a more complicated bicycle test. For young men the average results for step test at 40 cm. and bicycle test at 900 kg. per min. were: oxygen intake 2.11 ± 0.04 and 2.15 ± 0.02 litres per min. and pulse rate 130 ± 1.5 and 132 ± 1.9 per min. For young women the average values for step test at 33 cm. and bicycle test at 600 kg. per min. were: oxygen intake 1.56 ± 0.03 and 1.48 ± 0.02 litres per min., pulse rate 140 ± 1.6 and 138 ± 2.2 per min. Mechanical efficiency did not vary with body height or weight. An analysis of the pulse rate after and during work for 61 individual average results from step test and 66 from bicycle test gave a correlation coefficient $r = +0.77 \pm 0.04$ and a regression line $y = -21.4 + 0.77x$.

The pulse rate from 1 to 1.5 min. after work gives only a rough idea of the pulse rate during work if the results are compiled from different individuals, and cannot be used if the work is relatively light.—W. Godden.

JONGBLOED, J. and VAN GOOR, H. Zuurstof-toediening bij sport. [Giving oxygen during exercise.] *Nederland. Tijdschr. Geneesk.*, 1954, **98**, 491-497. [Physiol. Lab., Rijks Univ., Utrecht.] English summary.

The experiments were with a bicycle ergometer on which the subjects did a measured amount of work over short periods, usually 2 to 5 min. In intervals between spurts of work they breathed either oxygen or air. Sceptics experienced no improvement from breathing oxygen: those who expected to be improved by oxygen did better or felt better if they thought they breathed oxygen, whether it was oxygen or air, but did and felt worse when breathing oxygen if they thought it was air.—I. Leitch.

KARL, C. M., TUTTLE, W. W. and DAUM, K. Effect of protein source on specific dynamic action. *J. Amer. Dietetic Assoc.*, 1953, **29**,

1208-1210. [Dept. Physiol., State Univ. Iowa, Iowa City.]

The subjects were 14 healthy women aged 20 to 26. Each ate 2 test meals, similar in protein, energy and fat values, but the protein in one was entirely of animal origin and in the other of plant origin. Basal oxygen consumption was estimated before and for $4\frac{1}{2}$ hr. after the meal.

Each meal caused a significant increase in resting oxygen consumption, but the difference between the 2 meals in this respect was not significant.

KAHN, E. The effects of heat stress on patients suffering from cardiac failure and infantile malnutrition. *S. African Med. J.*, 1954, **28**, 110-112. [Dept. Paediat., Baragwanath Hosp., Johannesburg.]

Studies of which fuller details are to be published later were made of sweat secretion in control subjects and in infants with nutritional oedema and after partial recovery. Untreated oedematous infants secreted less than 100 mg. per 6 sq. in.; for all other subjects the range was from about 100 to 700 mg. [Time and temperature are not stated.] Congestive cardiac failure, with which a similar impairment is known to be associated, is not a feature of infantile malnutrition, but in affected infants there is evidence that cardiac output is small and peripheral circulation poor. The way in which this may handicap African infants living in ill ventilated huts with corrugated-iron roofs or carried by their mothers in thick woollen blankets is indicated.—D. Harvey.

HUTCHISON, H. G. and MABON, R. M. Studies on the environmental physiology of cattle in Tanganyika. 1. Preliminary observations on the seasonal diurnal variations in the rectal temperature of local Zebu cattle. *J. Agric. Sci.*, 1954, **44**, 121-128. [Livestock Res. Sect., Mpwapa, Tanganyika Territory.]

Morning and afternoon rectal temperatures of 10 Zebu cows were taken for 134 days. During the first 61 and the last 20 days all had access to pasture of poor quality; for the other 35 days 6 cows received 4 lb. concentrates, 15 lb. maize silage and 10 lb. poor quality hay and the other 4 cows received 10 lb. hay only.

N.A. and R., July 1954

The atmospheric shade temperature ranged at the beginning of the experiment from 64° to 76° F. and at the warmest period of the observations from 71° to 83° F. The diurnal variation in rectal temperature was approximately from 99.0° to 102.5° F. There was more variation in morning than in afternoon rectal temperatures. Morning temperatures were significantly higher when the ration was supplemented, but afternoon temperatures were not affected. There was a significant negative correlation between atmospheric temperature and the daily mean rectal temperature of the cows in the morning. The physiological implications of the results are briefly discussed.

RAGAB, M. T., GHANY, M. A. and ASKER, A. A. **Effect of shading and sprinkling on cattle and buffaloes in Egypt.** *Indian J. Vet. Sci.*, 1953, **23**, 205-215. [Animal Breeding Dept., Fac. Agric., Fouad I Univ., Cairo.]

After being exposed to sun for 2 hr. 8 buffaloes, 9 Egyptian cows, 2 Jerseys, 3 pure Shorthorns and 8 grade Shorthorns were subjected to different cooling treatments and the body temperature and respiration and pulse rates were measured hourly.

Shading, indoor and outdoor, after sprinkling with water for 3 or 5 min. decreased body temperature more than shading alone. When the time spent in shade was increased from 1 to 2 hr. body temperature was further reduced in all except the native cattle. Respiration rate followed the same general trend as body temperature. There was no consistent change in pulse rate.

FITZGERALD, L. R. **The oxygen consumption of neonatal mice.** *J. Exp. Zool.*, 1953, **124**, 415-425. [Div. Anat., Med. Units Div. Univ. Tennessee, Memphis.]

By means of Warburg manometers and constant temperature water-baths, oxygen consumption was estimated in mice during the first 5 days of life. At 35° C. total oxygen consumption closely followed the wet weight, with an average of about 1.9 ml. per g. per hr., which is somewhat higher than that reported for adult mice. The Q_{O_2} was approximately 12.0. The rate of oxygen consumption fell more or less linearly with falling temperature from 35° to 10° C. and then began to level off. There was no difference attributable to strain, sex, time of day, time after feeding or activity.—D. Duncan.

3270

JACOBSON, F. H. **Calorimetry of rats immersed in cool water.** *Amer. J. Physiol.*, 1954, **176**, 287-296. [Dept. Physiol., Sch. Med., Univ. Rochester, N.Y.]

Vol. 24, No. 8

Immobilised rats were immersed to the neck in 1500 ml. water at 20° C. for periods of up to 90 min. Temperatures of colon and of calorimeter water were measured at 6-min. intervals, and heat production was measured by indirect calorimetry. Colonic temperature fell rapidly at first and then slowly approached a value of about 24.0° C. The calorimeter water rose to about 22.5° C., the colonic always being above the water temperature. Heat production fell slowly, after a brief rise on immersion. From the data obtained, and assuming a constant unmeasured heat loss, the specific heat of the rat is estimated to be 0.96. The coefficient for combining deep and surface body temperatures, for the calculation of the rate of heat loss, is estimated to be 0.53.—S. D. Morrison.

WILHELMJ, C. M., MEYERS, V. W., MILANI, D. P., McDONOUGH, J. R., RACHER, E. M., MCGUIRE, T. F., WALDMANN, E. B. and MCCARTHY, H. H. **The effect of diet on the blood pressure and heart rate of normal dogs. Protein and carbohydrate.** *Circulation Res.*, 1953, **1**, 419-427. [Dept. Physiol., Sch. Med., Creighton Univ., Omaha, Nebr.]

Trained dogs were fasted until the blood pressure fell to a stable value and were then fed on isocaloric diets, high in protein or in carbohydrate, either at low maintenance level or at twice this amount. At the low level of feeding blood pressure and pulse rate rose promptly but moderately above the fasting levels, but there was no significant difference between the effects of the 2 types of diet. At the higher level of energy intake the systolic blood pressure and pulse rate rose significantly higher on the high-carbohydrate than on the high-protein diet. Addition of 25 g. NaCl to the high-carbohydrate diet caused a further rise of blood pressure. When a diet of half meat, half crackers was given there was evidence of an antagonistic effect on blood pressure between meat and carbohydrate.—W. Godden.

ERIKSSON, S. and KIVIMÄE, A. **Diurnal variation of food consumption and carbon dioxide production in laying hens.** *Acta Agric. scand.*, 1954, **4**, 71-77. [Inst. Animal Nutrit., Royal Agric. Coll., Uppsala.]

Six laying hens were housed in individual cages in a room lit usually from 8 a.m. to 10 p.m. On one day a week lighting was continued for 24 hr. and feed consumption was measured every 2 hr. In each period from 9 a.m. to 7 p.m. the mean consumption lay between 14 and 16 g., but in the remainder of the 24 hr. consumption was significantly lower, from 7 to 11 g.

Measurements of carbon dioxide production on each of these hens for a 2-day period also suggested a 24-hr. rhythm, but the differences between periods were less. They ranged from a mean 2-hourly production of 6.1 g. CO₂ between 7 and 9 a.m. to one of 7.1 g. between 5 and 7 a.m.

LOURAU, M. L'absorption intestinale du glucose est-elle un phénomène réversible? [**Is intestinal absorption of glucose a reversible phenomenon?**] *C.R. Acad. Sci.*, 1954, **238**, 842-844.

Absorption of glucose was studied by the method of Cori in guineapigs with high blood glucose produced by intramuscular injection of glucose. Passage of glucose from the blood into the intestine was not brought about by alterations in the concentration of glucose solution ingested. It is concluded that in the intact animal absorption is irreversible.

Disappearance of glucose from the gut was slight at blood sugar levels of 700 to 800 mg. per 100 ml. and was completely arrested when blood sugar reached 1000 mg. per ml.—D. Duncan.

3275

LOURAU, M. Glycémie et absorption intestinale du glucose. Recherches sur l'intestin isolé. [**Blood sugar and intestinal absorption of glucose. Research on the isolated intestine.**] *C.R. Acad. Sci.*, 1954, **238**, 936-938.

Glucose was injected into a segment of guinea-pig's intestine isolated *in situ* between 2 ligatures. The segment was that between the hepato-renal flexure of the duodenum and the middle of the jejunal loop below the ligament of Treitz. High blood sugar levels were produced by injection of 50 per cent. glucose.

Two types of absorption curve were obtained, depending on the presence or absence of glucose in the intestine before the experiment began. If glucose was previously absent absorption fell quickly, but if several experiments were made on the same loop absorption increased. Raising the blood sugar level significantly depressed absorption and prevented the increase in successive experiments. This suggests a direct effect of the blood sugar on absorption in intact animals.—D. Duncan.

3276

HESTRIN-LERNER, S. and SHAPIRO, B. **Absorption of glucose from the intestine. 1. *In vitro* studies. 2. *In vivo* and perfusion studies.** *Biochem. biophys. Acta*, 1953, **12**, 533-541 ;

1954, **13**, 46-60. [Lab. Pathol. Physiol., Hebrew Univ., Jerusalem.] French and German summaries.

1. When saline solutions containing equimolar concentrations of glucose were introduced into the lumen of the isolated small intestine of the rat and formed the surrounding fluid, a decrease in concentration of glucose occurred in the surrounding fluid, but this was slight in comparison with absorption from the lumen. The glucose that disappeared from the lumen could not be recovered from the intestinal wall. When glucose containing ¹⁴C was placed in the lumen, the ¹⁴C passed to the outer fluid, but not as glucose or as CO₂; it was in a form that was not fermented by baker's yeast. Oxygen consumption by the isolated intestine was such that, assuming complete combustion, only 15 per cent. of the glucose absorbed could be accounted for, and as the ¹⁴C was not present as CO₂ the oxygen used can have been concerned with only partial combustion of glucose.

The substance containing ¹⁴C was isolated and purified. It was no known intermediary of glucose degradation and remains to be identified.

2. The absorption of glucose was studied in rats by comparison of the glucose concentrations in arterial and portal blood 5 to 12 min. after glucose was introduced into the small intestine, which was ligated at both ends, and also using the small intestine perfused with ox serum and red cells.

With the first method the expected excess of glucose in the portal blood did not occur, negative or only small positive values being found. The expected values were estimated from the glucose loss from the small intestine and the calculated blood flow in the portal vein. The introduction of glucose labelled with ¹⁴C showed more ¹⁴C in the portal vein than in the arterial blood, even though glucose was less. A considerable portion of the ¹⁴C was contained in a non-fermentable substance. Similar results were obtained with the second method. Some lactic acid was found, which could have accounted for one-quarter of the glucose lost. The use of glucose labelled with ¹⁴C showed that in 12 min. about one-third passed into the portal blood and two-thirds remained in the wall of the intestine.

N.A. and R., July 1954

The conclusion is drawn that glucose is metabolised in the gut epithelium to a non-fermentable substance which accumulates in the epithelium and passes slowly into the portal bloodstream. Complete combustion accounts for only a negligible part of the glucose absorbed.—A. T. Phillipson.

3277

KOMROWER, G. M. **Blood sugar levels in babies born of diabetic mothers.** *Arch. Dis. Childhood*, 1954, **29**, 28-33. [St. Mary's Hosps., Manchester.]

Blood sugar was estimated in cord blood and in heel blood taken at $\frac{1}{2}$, 1, 2, 4, 12 and 24 hr. after birth from 40 infants of diabetic mothers and 21 of normal mothers. Twenty-five of the infants of diabetic mothers were given 50 per cent. glucose by mouth, 2 g. in all, at intervals during the first 8 hr. of life. The results are shown in tables and graphs.

Blood sugar values of normal infants showed a wide scatter but no great rise or fall in individuals; 2 had values of 36 mg. per cent. or less but no clinical sign of hypoglycaemia. In the infants of diabetic mothers blood sugar fell during the first 2 or 3 hr. and then stabilised at a level below that of the normal infants. Little advantage resulted from administration of glucose. Though many blood sugar values below 35 mg. per cent. were found, only 4 infants showed clinical signs of hypoglycaemia; there was no evidence that hypoglycaemia contributed to the deaths of 5 infants of diabetic mothers.—W. M. Deans.

3278

CHOREMIS, K. B. and NICOLAIDES, P. Beitrag zum Stoffwechsel der Kohlenhydrate bei dystrophischen Säuglingen. [Metabolism of carbohydrates in dystrophic infants.] *Ztschr. Kinderheilk.*, 1954, **74**, 123-132. [Kinderärztl. Klin., Univ. Athens.]

The blood sugar curves of dystrophic infants after administration of glucose were much the same as those of normal children. The highest blood sugar values in both were found after 1 hr. and the lower level reached by the dystrophic infants was ascribed to the depletion of their blood and tissues. The descending portion of the dystrophic curves showed slight retardation, and the blood sugar values did not return to their original level within 3 hr., when the normal curves had reached subnormal levels. Similar differences between the dystrophic and eutrophic curves were found after administration of adrenaline, and of insulin combined with glucose. The experiments indicate that so far as glucose absorption is concerned, the dystrophic infant shows no disturbance but tolerates sugar well, even in quantities based not on its actual weight but on what its weight should be.—M. B. Richards.

MURDOCH, P. **Hyperglycaemia and haemorrhagic shock in pregnancy. Preliminary study.** *J. Obstet. Gynaecol. Brit. Empire*, 1953, **60**, 785-792. [Res. Dept., Royal Maternity Hosp., Glasgow.]

Blood samples were obtained from 40 patients in haemorrhagic shock at different stages of pregnancy or *post partum*.

The average blood sugar value was 222 mg. per 100 ml., range 110 to 364 mg. Shock of short duration produced little change in blood sugar, and only after about 30 min. was there an appreciable rise; it was avoided in 5 patients who received blood transfusion 10 to 15 min. after the development of shock. Whatever the cause of shock, *post partum* haemorrhage, accident, abortion or intraperitoneal haemorrhage, the longer it remained untreated the higher did the blood sugar rise. In accidental haemorrhage, however, the rise tended to be delayed. There was no evidence of a terminal fall, the highest value occurring an hour before death in a patient in profound shock. In response to treatment the blood sugar declined with the fall in pulse rate.—D. Duncan.

JONXIS, J. H. P. and HUISMAN, T. H. J. **The excretion of sugars after the intravenous administration of invert sugar.** *Arch. Dis. Childhood*, 1953, **28**, 446-449. [Child. Hosp., Univ. Groningen, The Netherlands.]

The children studied had been admitted to hospital with signs of shock associated with acute infectious diseases. They were given intravenous infusions, which during the last 24 hr. consisted of 10 per cent. solutions of glucose or invert sugar.

Sugar excretion in both groups was negligible, ranging from 0.4 to 2.2 per cent. of the amount administered. The average fluid loss, however,

was 1245 ml. in 24 hr. with glucose, against 1090 ml. with invert sugar. When the sugar infusions were given more rapidly, glucose loss increased. With invert sugar the loss of glucose increased but that of fructose remained almost negligible; the total loss was still less than half the loss from an equivalent amount of glucose.

In view of the smaller losses in both sugar and fluid, invert sugar is considered to be better than glucose for administration to children.

HÖRMANN, E. Über die Pathogenese des Milchsüßkernstars der weissen Ratte. [**Pathogenesis of lactose cataract in the white rat.**] *v. Graefes Arch. Ophthalmol.*, 1954, **154**, 561-573. [Forschungslab., Kinderklin., Univ. Munich.]

The author surveys the literature on galactose cataract and the metabolism of lactose and compares different hypotheses. From his own experiments he found that rats on a diet containing 70 per cent. of α - or β -lactose died in a few days in a condition of extreme emaciation. With 30 per cent. galactose and 40 per cent. oat flakes, degenerative changes occurred in the lens. Injection of cocarboxylase prevented these effects of lactose and galactose. It is suggested that lactose and galactose prevent the fermentative breakdown of carbohydrate, and that cocarboxylase inhibits the action of these sugars and prevents the development of galactose cataract. The cause of this cataract is assumed to be interference with the conversion of pyruvic acid into lactic acid in the lens.—M. B. Richards.

GOODALE, W. T. and HACKEL, D. B. **Myocardial carbohydrate metabolism in normal dogs, with effects of hyperglycemia and starvation.** *Circulation Res.*, 1953, **1**, 509-517. [Med. Clin., Peter Bent Brigham Hosp., Boston, Mass.]

For the method used see Title 2798, Vol. 24.

In dogs under light Nembutal anaesthesia the coronary sinus, pulmonary artery and a peripheral artery were intubated, and coronary blood flow, myocardial oxygen consumption, cardiac output and left ventricular work and efficiency were estimated. Four of the dogs were starved, receiving a reduced diet for 2 weeks and then nothing but water and vitamins for 18 days.

The amount of pyruvate, lactate, glucose and oxygen extracted by the myocardium from the

blood in normal dogs was directly related to the arterial level of each substance independently of the others and was not significantly correlated with coronary blood flow or left ventricular work. When arterial glucose concentration was raised by glucose infusion, lactate and pyruvate were increased, with corresponding increases in their coronary arterio-venous differences.

The mean total oxygen utilisation was 19.5 ± 1.5 ml. per 100 g. left ventricular myocardium per min. About two-thirds of this was potentially accounted for by lactate, pyruvate and glucose extraction, assuming complete substrate oxidation. However, at high arterial levels of lactate or glucose, the collective oxygen equivalents exceeded the simultaneous oxygen extraction, which may imply storage of metabolites at these levels of supply. The mean normal myocardial R.Q. from 14 observations was 0.91 ± 0.03 , closely correlated ($r = +0.90$) with the percentage of the total oxygen extraction attributable to carbohydrate uptake.

Starved dogs had high arterial pyruvate levels, but lactate and glucose did not differ significantly from normal. Extraction rates of all 3 metabolites were significantly reduced and the mean R.Q. was about 0.69, suggesting utilisation of fat. A metabolic block in carbohydrate oxidation is postulated to account for this.—D. Duncan.

HANKE, O. Untersuchungen über Blutzucker und Insulinhypoglykämie bei Hühnern. [**Studies of blood sugar and insulin hypoglycaemia in hens.**] *Ztschr. ges. exp. Med.*, 1953, **122**, 238-248. [Med. Klin., Univ. Greifswald.]

For 20 healthy fowls the average blood sugar value was 182 mg. per 100 ml. without definite difference between the sexes. After a 48-hr. fast the values remained within the normal range. Four hens with severe tuberculosis of the abdominal organs gave a lower blood sugar value than normal, and the value was reduced by fasting. Convulsions caused by strychnine or picrotoxin reduced blood sugar. In young males during the period of rapid growth blood sugar showed a steady increase, followed by a decrease after puberty. Insulin injections, intravenous or subcutaneous, reduced blood sugar, values as low as 31 mg. per 100 ml. being found. Male birds were more sensitive than females to insulin; shock was

N.A. and R., July 1954

always observed in adults, and convulsions in younger birds, but without fatal results. It is suggested that this greater sensitivity in the male may be due to an influence of the sex hormones.

STEPANENKO, B. N. and AFANAS'EVA, E. M. O stroenii glikogenov razlichnykh vidov zhivotnykh. [The structure of glycogens from different species of animals.] *Dokl. Akad. Nauk S.S.S.R.*, 1953, **90**, 1095-1098. [Lab. Fiziol. Chim., Akad. Nauk SSSR.]

Glycogens from rabbits and frogs at different times of the year, studied with respect to molecular weight, chain unit and absorption curves for compounds formed with iodine, and the effect of β -amylase, showed structural differences. The molecules of glycogen from frogs as a rule were more compact than those of glycogen from rabbits.

[Glycogen and potassium contents of blood, liver, muscle and kidney of rats after starvation, glucose feeding, insulin and adrenaline.] *Ztschr. ges. exp. Med.*, 1953-54, **122**, 564-577. [Physiol. Chem. Inst., Univ. Münster, Westphalia.]

Glycogen and K were estimated in the liver, muscle and kidney of rats, to test the theory that K is taken up and bound in the formation of glycogen. To achieve the greatest possible changes in the glycogen content of the tissues, the animals were subjected to starvation, loading with glucose, or injection with insulin or adrenaline. In spite of

changes in the glycogen content the K content, on both dry and moist basis, remained constant. It is concluded that combination with K does not take place in glycogen synthesis.

Observations made in the course of the work showed that red and white thigh muscle contained equal amounts of K, and that the K content of muscle was greater in spring than in winter.

GIDEZ, L. I. and KARNOVSKY, M. L. The metabolism of C^{14} -glycerol in the intact rat. *J. Biol. Chem.*, 1954, **206**, 229-242. [Dept. Biol. Chem., Harvard Med. Sch., Boston, Mass.]

Glycerol labelled with ^{14}C in the α - or β -position was given intravenously, intraperitoneally or by stomach tube to fasting rats. Whatever the route of administration, about the same proportion of the amount given, from 30 to 238 mg., was converted to CO_2 . From 70 to 100 per cent. of blood sugar and 15 to 39 per cent. of liver glycogen was synthesised from glycerol. The specific activity of blood lipids was parallel to that of liver lipids. Liver triglyceride glycerol rapidly reached a specific activity about 3 times that of phospholipoid glycerol and declined in activity much more rapidly than the latter.—G. A. Garton.

MURTHY, H. B. N., SWAMINATHAN, M. and SUBRAHMANYAN, V. Effects of partial replacement of rice in a rice diet by tapioca flour on the metabolism of nitrogen, calcium and phosphorus in adult human beings. *Brit. J. Nutrition*, 1954, **8**, 11-16. [Central Food Technol. Res. Inst., Mysore.]

Experiments with rats (Abst. 3520, Vol. 24) suggested a study of the effects on man of replacing with tapioca flour 25 per cent. of the rice in a typical South Indian diet, particulars of which are given. The subjects were 6 healthy male laboratory workers aged from 22 to 37. They ate the rice diet and the rice-tapioca diet for 2 successive 12-day periods; urine and faeces were collected during the last 5 days of each period.

Vol. 24, No. 3

N retention was much the same on both diets. Two subjects were losing Ca on the rice diet but on the rice-tapioca diet all 6 retained Ca and the difference in average Ca retention was significant. Average P retention was also significantly greater on the rice-tapioca diet, although the P intake was about the same; this is ascribed to the fact that tapioca contains very little phytate P.

W. M. Deans.

BEAL, J. M., FROST, P. M. and SMITH, J. L. (with FELTS, J.) The influence of caloric and potassium intake on nitrogen retention in man. *Ann. Surg.*, 1953, **138**, 842-845. [Surg. Metabol. Lab., Dept. Surg., Univ. California, Los Angeles.]

Three adult male surgical patients were fed intravenously with solutions of glucose, alcohol, saline and protein hydrolysate. The patients were in positive N balance when 80 m. equiv. K were added, but in negative balance when K was not given. Reduction of glucose intake from 500 to 100 g. daily in a patient given K reduced N retention, but the patient remained in positive N balance.—F. C. Aitken.

3295

MUNRO, H. N. and WIKRAMANAYAKE, T. W. **Absence of a time factor in the relationship between level of energy intake and protein metabolism.** *J. Nutrition*, 1954, **52**, 99–114. [Dept. Biochem., Univ. Glasgow.]

When dogs on a diet of casein, sucrose, fats, salts and vitamins were given extra glucose with the daily meal, urinary N output fell: when the glucose was given 7 or 12 hr. after the meal, the immediate fall was progressively less, but if the treatment was continued for several days the N retention was similar whether the glucose was given at the same time as or 12 hr. after the main meal.

When young adult men on adequate diets took 200 g. sucrose with their meals or 5½ hr. after the last meal of the day, there were similar falls in N output from the first or the second day of the experiment, respectively. Similarly, when rats were given extra carbohydrate or extra fat at the same time as or 12 hr. apart from the main meal, there were increases in N balance.

It is concluded that protein utilisation is affected in two ways by carbohydrate: firstly, the presence of some carbohydrate in the protein meal improves utilisation; secondly, extra carbohydrate and fat, whether taken at the same time as or apart from the protein, act interchangeably as energy sources in sparing protein.—C. Warner.

QUINN, M., KLEEMAN, C. R., BASS, D. E. and HENSCHER, A. **Nitrogen, water and electrolyte metabolism on protein and protein-free low-calorie diets in man. 1. Water restriction. 2. Adequate water intake.** *Metabolism*, 1954, **3**, 49–67; 68–77. [Biochem. Branch, Quartermaster Climatic Res. Lab., Lawrence, Mass.]

1. Ten healthy young men were given an adequate diet for a control period of 13 days during which balance studies were made. The men were then divided according to body fat and weight into 2 groups of 5 and were given for 9 days 800 ml. water daily and a synthetic diet supplying about 900 Cal. For one group the diet contained 43.14 g. protein as egg albumin; for the other group the protein was replaced by carbohydrate. The diets were not made equal in mineral content.

Data obtained from the experimental period were for the protein and non-protein group, respectively, mean bodyweight loss 5.5 and 4.1 kg.; mean body fat loss 2.7 and 2.0 kg.; mean cumulative negative N balance 56.4 and 59.9 g.; mean negative water balance 5703 and 4130 ml.; mean 24-hr. urinary creatinine output 1.70 and 1.46 g. There was no appreciable difference in electrolyte balance or in losses of circulating Hb, packed cell volume and total circulating protein between the 2 groups. Ketosis occurred in the protein group and in one subject in the non-protein group. The results showed that added protein at the 900-Cal. level increased the loss of body water without appreciably improving N balance.

2. In a second experiment 2 groups of 5 men were given diets similar to those in the first experiment and all subjects drank each day for 9 days 27 ml. water per kg. lean body mass. Daily water intakes in the protein and non-protein groups were, respectively, 1747 and 1767 ml. Mean cumulative negative water balances were 4704 and 4807 ml. Mineral and N balances followed the pattern of the first experiment.

F. C. Aitken.

3297

SQUIRE, J. R. **The nephrotic syndrome.** *Brit. Med. J.*, 1953, **ii**, 1389–1399. [Dept. Exp. Pathol., Univ. Birmingham.]

This lecture is based on a study of 19 patients exhibiting proteinuria, including 8 with the uncomplicated nephrotic syndrome, defined as oedema, protein in urine and low albumin in blood, without hypertension, electrolyte disorder, retention of N.P.N. or appreciable excess of red blood cells in the urine.

Changes in colloid osmotic pressure of plasma, as measured by an apparatus described, are discussed in relation to plasma volume; serum protein and losses and replacement of the several fractions are described.

N balance studies are recommended. Patients with long histories of proteinuria were grossly deficient in body protein. The low urea output is considered to be a manifestation of N conservation for plasma protein replacement. At the same time, amino-acid excretion may be high.

Prognosis and treatment are discussed, especially the need for high-protein feeding.

eosinophils. *J. Clin. Endocrinol.*, 1953, **13**, 1502-1506. [2. Med. Clin., Univ. Helsinki.]

After an overnight fast 20 healthy adults received 200 g. water or solutions of 0.5 g. gelatine, 0.5 g. casein or 0.3 g. tyrosine per kg. bodyweight. Eosinophil counts made 1, 2, 4 or 6 hr. later showed that gelatine had no effect, but casein and tyrosine caused decreases of 33 per cent., the peak being attained in 4 hr. In 6 other subjects 0.6 g. tyrosine per kg. bodyweight produced a decrease of 43 per cent. after 4 hr.—W. Godden.

3300

MUIRHEAD, E. E., JONES, F. and GRAHAM, P. (with BROOKS, B. and LESCH, W.) **Hypertension following bilateral nephrectomy of the dog. The influence of dietary protein on its pathogenesis with emphasis on its development in the absence of "extracellular fluid" expansion.** *Circulation Res.*, 1953, **1**, 439-453. [Dept. Pathol., Southwestern Med. Sch., Univ. Texas, Dallas.]

By increasing the intake of casein after removal of both kidneys high blood pressure was produced in dogs even without high salt intake. The hypertension appeared early in the experiment and was not associated with increase in either blood or extracellular fluid volume. Vomiting and diarrhoea were slight, Na, Ca and fluid balances were maintained, and bodyweight tended to fall as hypertension mounted.

Losses of K and N appeared to be due mainly to tissue breakdown, and the relatively greater loss of N suggested a redistribution of K away from the extracellular fluid.

In the pathogenesis of hypertension after nephrectomy, not only tissue breakdown and redistribution of K and Na, but also diet may be concerned.—W. A. Greig.

3301

MARSHALL, M. W. and WOMACK, M. **Influence of carbohydrate, nitrogen source and prior state of nutrition on nitrogen balance and liver composition in the adult rat.** *J. Nutrition*, 1954, **52**, 51-64. [Bur. Human Nutrit., Agric. Res. Admin., Washington, D.C.]

Rats received for 3 weeks diets containing the essential and non-essential amino-acids at levels of 0.1 per cent., sucrose or maize dextrin, salts, fats and vitamins, with or without previous protein depletion on a similar but N-free diet.

The N balances were more negative and the accumulation of fat in the liver was much greater with sucrose than with dextrin. Raising the level of the essential amino-acids to 0.2 per cent. made the N balances positive and eliminated the differences due to the carbohydrate source. When extra glutamic acid was given, N balances improved

in rats given sucrose but not in those given dextrin. The livers of rats given sucrose contained more protein than those of the animals given dextrin, except with the N-free diets.

It is suggested that maize dextrin in the diet in some way facilitates the use of liver protein or its precursors, and so reduces N output.—C. Warner.

HARPER, A. E., MONSON, W. J., ARATA, D. A., BENTON, D. A. and ELVEHJEM, C. A. **Influence of various carbohydrates on the utilization of low protein rations by the white rat. 2. Comparison of several proteins and carbohydrates. Growth and liver fat.** *J. Nutrition*, 1953, **51**, 523-537. [Dept. Biochem., Univ. Wisconsin, Madison.]

Groups of 6 weanling rats were fed to appetite. The basal diet had the percentage composition: sucrose 81.6, casein 9.0, DL-methionine 0.3, maize oil 5.0, salt mixture 4.0 and choline chloride 0.13, with vitamins. Supplements were included at the expense of sucrose, and casein was omitted when other proteins were tested.

In every experiment with 9 per cent. casein, rats receiving dextrose grew 2 or 3 times as fast as those on sucrose, with cerelose intermediate. Deposition of liver fat was greatest with sucrose or fructose and least with dextrose or cerelose. The effect of dextrose on growth occurred also when the casein was replaced by wheat gluten supplemented with lysine, egg albumin, fibrin or an amino-acid mixture. With wheat gluten or fibrin liver fat was low whatever the carbohydrate source, and with albumin it was high, but dextrose decreased it when amino-acids were given. Addition of gelatine, zein or extra casein to the basal diet reduced liver fat deposition.

In pair-feeding experiments in which the food intake of rats fed on the dextrose diet was kept down to that of rats receiving sucrose, the difference in growth was slight, but the rats receiving dextrose had less liver fat. In a long experiment the liver fat of the animals receiving sucrose, which rose to 32.9 per cent. after 4 weeks, dropped after 12 weeks to 14 per cent., the same as that of rats receiving dextrose.

Xanthine oxidase activity in liver homogenates was lower than in rats fed on 18 per cent. casein, especially in those which received sucrose.

It is suggested that all the results could spring from improved utilisation of dietary protein when dextrose replaces sucrose.—D. Duncan.

3303

STENRAM, U. **The nucleolar size in the liver cell of rats fed high and non protein diets.** *Exp. Cell. Res.*, 1953, **5**, 539-541. [Dept. Histol., Univ. Lund.]

Groups of 4 weanling white rats were given diets with or without 22 or 3 per cent. crude casein with fat, sucrose, salt mixture and vitamins. After 10 days they were killed and the middle lobe of the liver was fixed. Thin paraffin sections stained with gallocyaminchromalum showed the nucleoli to be larger in rats having little or no protein. No difference of effect was found between 3 per cent. and no protein, and there was no difference in the number of nucleoli present in liver sections from the 3 groups.—A. M. Copping.

3304

MANNELL, W. A. and ROSSITER, R. J. **Nutritional deficiency and Wallerian degeneration in the rat. 1. Effect of protein depletion on the concentration of nucleic acid and phospholipid in intact and sectioned nerves.** *Brit. J. Nutrition*, 1954, 8, 44-55. [Dept. Biochem., Univ. W. Ontario, London, Canada.]

The percentage composition of the basal diet was: salt mixture 4, vitamin mixture 1, cellulose 5, brewer's yeast 2, casein 20, maize starch 48, cod liver oil 0.1, maize oil 3.9 and water 16. A protein-deficient diet was produced by replacing the casein with an equal quantity of maize starch. The protein-deficient rats had received the latter diet to appetite for 69 days. Age controls received the basal diet during the same period; weight controls received the basal diet for 16 days and were killed when their bodyweight was the same as that of depleted rats; the weight and age controls received restricted amounts of the basal diet so that their mean bodyweight followed that of the depleted rats.

The depleted rats lost more than 25 per cent. of their initial bodyweight. One sciatic nerve was cut in the thigh of each rat 8 days before the animal was killed. For control rats there was a highly significant correlation between bodyweight and the wet weight of the sciatic nerve per unit length. For a given bodyweight the mean nerve weight of protein-depleted or weight and age control rats was significantly greater than in the other groups. Protein depletion caused some loss in nerve weight as compared with age controls.

Nucleic acid concentration in the nerves of depleted rats was less than in weight controls, but similar to that in age controls. Phospholipin concentration was related to weight rather than to age. Protein depletion did not affect nucleic acid concentration, but phospholipin increased. Nucleic acid increased and phospholipin decreased in the cut nerves, and these changes were little affected by protein depletion.—D. Duncan.

HARA, M. **Experimental study on treatment of wound in case of hypoproteinosis.** *Nagoya J. Med. Sci.*, 1953, 16, 12-26. [2. Dept. Surg., Sch. Med., Univ. Nagoya.]

In all, 262 mice were used. The basal diet consisted, in g., of casein 8, arrowroot starch 24, lard 6, "Ebios" 1.8 and salt mixture 3, with 12 drops of cod liver oil. In a protein-free diet the casein was replaced by 8 g. starch. After 2 weeks the liver protein value in mice of the deprived group was about half that in the normal group. Healing of superficial wounds was delayed by 6 or 8 days in protein-deficient, as compared with normal, rats. The effects of essential amino-acids, singly and in combination, are reported; methionine, lysine and tryptophan were most effective in promoting healing. Folic acid and vitamin B₁₂ supplements were ineffective in complete protein deficiency, but they enhanced the value of a methionine supplement.—D. Duncan.

3307

MEYER, J. H. **Interactions between a high concentration of dietary sodium chloride and various levels of protein when fed to the growing rat.** *J. Nutrition*, 1954, 52, 137-154. [Dept. Animal Husb., Univ. California, Davis.]

Rats received diets containing from 10 to 55 per cent. casein and 0.5 or 15.5 per cent. NaCl, both to appetite and by paired feeding, and weight gain, food and water consumption, plasma albumin, kidney weight, extracellular fluid, digestibility of organic matter and N, and N retention were measured.

The principal effects were decreased food consumption, gain per g. casein consumed, plasma albumin and N retention, and increased kidney weight, water consumption, N digestibility and urinary N loss on increasing the salt content of the diet; increased kidney weight with increasing casein on the high- but not on the low-salt diet; and increased extracellular fluid on the low-protein, high-salt diet.—C. Warner.

3308

HUGOT, D., CAUSERET, J. and FLANZY, M. **Effet de l'alcool éthylique sur la perte intestinale et sur la perte rénale d'azote au cours de l'inanition azotée.** [Effect of ethyl alcohol on intestinal and renal loss of nitrogen during nitrogen deprivation.] *C.R. Acad. Sci.*, 1954, 238, 619-621.

Rats received a ration of percentage composition starch 50, sucrose 32, arachis oil 12, salt mixture 4, agar 2, with vitamins. It contained 40 mg. N per 100 g. Groups received daily by tube, per 100 g. bodyweight, 6 ml. 10 per cent. ethanol, 6 ml. red wine diluted to contain 10 per cent. ethanol, or 6 ml. water. Urinary and faecal N were estimated for 4 successive 5-day periods.

The alcohol as such or as wine had no effect on the excretion of faecal endogenous N; it caused a marked but transitory rise in urinary N which could not be explained as a washing out of breakdown products.—W. Godden.

3309

SAUBERLICH, H. E., CHANG, W. Y. and SALMON, W. D. **The comparative nutritive value of corn of high and low protein content for growth in the rat and chick.** *J. Nutrition*, 1953, **51**, 623-635. [Dept. Animal Husb., Agric. Exp. Stat., Alabama Polytech. Inst., Auburn.]

Maize of protein content 6.8 to 13.6 per cent. was used. Weanling Sprague Dawley rats and day-old Leghorn chicks were the test animals.

When the high- and low-protein maize samples were given on the basis of equal proportions of maize in the diet the high-protein samples gave the better growth, but on the basis of equal protein content in the diets the low-protein maize was better. The low-protein maize was deficient in lysine, tryptophan, isoleucine, threonine and valine and possibly other amino-acids. The high-protein maize was deficient in lysine and tryptophan only, and not so severely so as the low-protein maize. Soya bean meal was the most efficient natural protein supplement and gave the most satisfactory results with the high-protein maize diet.—P. C. Jowsey.

3310

SURE, B. (with EASTERLING, L., DOWELL, J. and CRUDUP, M.) **Protein supplementation. Relationships between milled rice and milled white corn meal.** *J. Agric. Food Chem.*, 1953, **1**, 1207-1208. [Univ. Arkansas, Fayetteville.]

Since previous work (Title 1925, Vol. 16; Abst. 2309, Vol. 17) had shown that the proteins of milled rice were biologically superior to those of milled maize and milled wheat, their supplementary value along with these cereals was investigated. Wistar albino rats, 30 days old and weighing from 50 to 55 g., in groups of 12 males and 12 females, were fed for 8 weeks on diets containing 7 per cent. of protein entirely supplied by milled wheat flour or 6 per cent. of protein entirely supplied by milled white maize meal, or the same with half or a third of the wheat flour or maize meal replaced by milled rice. The other constituents of the diet were cellu flour 2, salt mixture 4, vegetable

shortening 2, cod liver oil 2 and wheat germ oil 1 per cent., with cerelese, and crystalline B vitamins were given to each rat daily as follows: vitamin B₁, riboflavin, nicotinic acid, pyridoxine 25 µg. each, Ca pantothenate 150 µg., p-aminobenzoic acid 3 mg., choline chloride 6 mg., inositol 1 mg. The rats were weighed weekly and protein efficiency ratios (weight gain per g. protein intake) were calculated.

When half the wheat protein was replaced by rice protein average weight gain over 8 weeks increased by 114 per cent. and protein efficiency ratio by 86 per cent. With one-third replacement the increases were 54 and 56 per cent. With maize meal the supplementary value of rice was even greater, the increases being 236 and 165 per cent. for half replacement and 190 and 148 per cent. for one-third replacement. The effect is ascribed to the proteins and amino-acids of the rice and not to any other substance present in it.

It is suggested that poor people subsisting mainly on maize in such regions as the southern United States, Mexico, Guatemala, South Africa and Yugoslavia should grow more rice where conditions are suitable.—W. M. Deans.

3311

KADKOL, S. B., MURTHY, H. B. N., PINGALE, S. V. and SWAMINATHAN, M. **Effect of methyl bromide fumigation on the biological value of the proteins in rice and groundnut.** *Bull. Central Food Technol. Res. Inst., Mysore*, 1953, **3**, 19-20.

Fumigation of raw undermilled rice and groundnut kernels with methyl bromide did not significantly decrease the methionine content of their protein or affect their protein efficiency ratio for rats as estimated by the method of Osborne *et al.* (*J. Biol. Chem.*, 1919, **37**, 223).—J. S. Thomson.

3312

RAO, G. R., MURTHY, H. B. N. and SWAMINATHAN, M. **Supplementary relations of Bengalgram and groundnut proteins to bajra (*Pennisetum typhoideum*) proteins.** *Bull. Central Food Technol. Res. Inst. Mysore*, 1953, **3**, 44.

In experiments with rats it was found that the protein efficiency ratio (Osborne *et al.*, *J. Biol. Chem.*, 1919, **37**, 223) of bajra (*Pennisetum typhoideum*) protein was higher than that of wheat protein when given at a 10 per cent. level of protein intake. The proteins of groundnut cake and Bengal gram (*Cicer arietinum*) supplemented those of bajra.—J. S. Thomson.

3313

SIMAKOV, P. B. **Znachenie globina i gema v pitanii. [Nutritional importance of globin and haem.]** *Vop. Pitani.*, 1954, **13**, 7-11.

[Lab. Physiol. Pitan. Rastushch. Organ., Inst. Pitan., Akad. Med. Nauk SSSR, Moscow.]

Rats, one month old, were given an artificial diet containing only 1.7 per cent. protein (brewer's yeast). When 25 per cent. or more of the original weight had been lost, 16 per cent. bovine globin was added to the diet for 40 days. Some animals were given, in addition, 35 mg. *isoleucine* for 4 days. A third group were given 9 per cent. casein for 6 days and for a further 7 days also 30 mg. haem. The methods of preparation of globin and haem are described. Weight changes and blood changes were studied in all animals.

The animals given globin gained little weight, 0.26 g. in 24 hr., but became more active and healthier in appearance. Addition of *isoleucine* increased weight gain to 1.5 to 4.0 g. in 24 hr. In animals given haem, weight increases of the order of 3 g. in 24 hr. were recorded independently of increases attributed to casein.

Globin raised the blood globin and haematin content slightly and the protein of the red-cell stroma considerably, but had no influence on catalase activity.

Haem assisted in the rise of blood haematin, slightly raised blood globin and protein of red-cell stroma, but did not affect catalase activity.

D. W. Taylor.

3314

MCCAUGHY, M. L., OWEN, E. C., HENRY, K. M. and KON, S. K. **The utilization of non-protein nitrogen in the bovine rumen. 8. The nutritive value of the proteins of preparations of dried rumen bacteria, rumen protozoa and brewer's yeast for rats.** *Biochem. J.*, 1954, **56**, 151-156. [Hannah Dairy Res. Inst., Kirkhill, Ayr.]

Dried preparations of rumen bacteria and rumen protozoa were compared with dried brewer's yeast at the 8 per cent. protein level as the sole source of N for growth of young rats.

The biological values of dried bacteria and dried protozoa were the same and greater than that of the yeast. True digestibility was greater for rumen protozoa than for bacteria.

The relations between the rumen bacteria and their host are discussed.—A. T. Phillipson.

3315

HOLMES, P., MOIR, R. J. and UNDERWOOD, E. J. **Ruminal flora studies in the sheep. 5. The amino-acid composition of rumen bacterial protein.** *Austral. J. Biol. Sci.*, 1953, **6**, 637-644. [Inst. Agric., Univ. W. Australia, Netherlands.]

For previous papers see Abst. 574, Vol. 24.

Rumen bacteria were separated from plant residues and protozoa and the amino-acid composition (amino-N as percentage of protein N) was

studied. The protein contained about half as much methionine and *isoleucine* as whole egg protein. It is considered that the nutritional value of rumen bacteria as a source of protein is limited by these two amino-acids.

Bacterial proteins from sheep grazing and on dry rations were closely similar in composition.

A. T. Phillipson.

3316

ROSE, W. C., HAINES, W. J. and WARNER, D. T. **The amino acid requirements of man. 5. The rôle of lysine, arginine, and tryptophan.** *J. Biol. Chem.*, 1954, **206**, 421-430. [Div. Biochem., Noyes Lab. Chem., Univ. Illinois, Urbana.]

For methods see the earlier papers (Absts. 2222, Vol. 20; 663, Vol. 21 and 819, Vol. 22). The absence of lysine or tryptophan from the diet produced negative N balance, loss of appetite, fatigue and nervousness. No effect was seen when arginine was omitted from the diet.

This paper completes the qualitative study of the amino-acids essential for adult man; valine, leucine, *isoleucine*, threonine, methionine, phenylalanine, lysine and tryptophan are indispensable, but all others could be omitted from the diet without harm.—C. Warner.

3317

LO BIANCO, S. **Determinazioni dell'aminoaciduria nel lattante mediante cromatografia su carta. [Estimation by paper chromatography of amino-acids in the urine of infants.]** *Boll. Soc. ital. Biol. sper.*, 1953, **29**, 1134-1135. [Ist. Clin. Pediat., Univ. Parma.]

Urine of 24 healthy babies up to a year old was analysed for amino-acids by paper chromatography. Artificially fed babies excreted more amino-acids than those that were breast fed. The amount excreted increased with age during the first year. Only small amounts of essential amino-acids and traces of sulphur amino-acids were excreted.—E. M. Hume.

3318

JONXIS, J. H. P. **Amino-acidurie. [Amino-aciduria.]** *Nederland Tijdschr. Geneesk.*, 1954, **98**, 598-601. [Groningen.]

SANDLER, M. and PARE, C. M. B. **Starvation amino-aciduria.** *Lancet*, 1954, **266**, 494-495. [Shorncliffe Military Hosp., Kent.]

Chromatograms of urine from 15 people before and after starvation for from 36 to 108 hr. showed T-spot (β -amino-isobutyric acid) as follows: in 2 before and during starvation, in 9 during starvation, in 4 neither before nor during starvation.

N.A. and R., July 1954

The implications of the findings are discussed with special reference to malignant disease.

MANN, G. V., FARNSWORTH, D. L. and STARE, F. J. **An evaluation of the influence of DL-methionine treatment on the serum lipids of adult American males.** *New Engl. J. Med.*, 1953, **249**, 1018-1019. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

A group of 24 men whose blood lipoproteins of the S₇ 12-20 class were 50 mg. or more per 100 ml. were given 3 g. methionine by mouth in 3 equal doses daily for 6 weeks. They continued their activities and diet without change. Blood samples were collected fortnightly during the treatment and 2 weeks after it ceased.

The data for total cholesterol content and for the levels of S₇ 12-20 and S₇ 20-100 lipoproteins were analysed statistically; no evidence was found that the serum lipids were influenced by the relatively large amount of methionine ingested.

DENTON, A. E. and ELVEHJEM, C. A. **Availability of amino acids in vivo.** *J. Biol. Chem.*, 1954, **206**, 449-454. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Dogs with cannulae in the portal vein were given semipurified diets in which casein, beef or zein was the protein constituent; the concentrations of the 10 essential amino-acids in the portal blood were estimated at intervals after feeding. With casein or beef there was an increase in the amino-acid concentration of the blood within an hour, and earlier with casein than with beef. With zein there was an initial decrease, followed by an increase at 6 hr.; the decrease was possibly due to initial absorption of carbohydrate and delayed absorption of amino-acids. The amino-acids present in highest concentration in the diet showed the greatest increases in their concentration in portal blood.—C. Warner.

3323

DENTON, A. E. and ELVEHJEM, C. A. **Amino-acid concentration in the portal vein after ingestion of amino-acid.** *J. Biol. Chem.*, 1954, **206**, 455-460. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

An amino-acid mixture was substituted for the protein in the diets described above. Rapid

absorption took place, with peaks in the portal blood concentration at 1, 2½ and sometimes 6 hr. When sucrose replaced the N source the blood amino-acid concentration decreased initially and then increased at about 6 hr.

Phenylalanine, tryptophan and possibly leucine were not absorbed so rapidly as the other amino-acids.—C. Warner.

RICHARDSON, L. R., BLAYLOCK, L. G. and LYMAN, C. M. **Influence of dietary amino-acid supplements on the free amino-acids in the blood plasma of chicks.** *J. Nutrition*, 1953, **51**, 515-522. [Dept. Biochem. Nutrit., Texas Agric. Exp. Stat., College Station.]

Chicks fed from hatching to 6 weeks of age on a basal ration of groundnut meal 32 parts, minerals 2.5, vitamins and ground milo to 100 finished with

a mean weight of 364 g. Groups of 25 birds fed on the same ration supplemented with either 0.4 per cent. DL-methionine, 0.2 per cent. L-lysine, or both together finished with mean weights of 330, 443 and 567 g., respectively.

Some free amino-acids were estimated in pooled plasma samples. Samples from each group gave values for tryptophan within the range of 60 to 64 μ g. per ml. The control group gave plasma containing 29 μ g. methionine per ml., and the supplemented groups 61, 28 and 64 μ g., respectively. For lysine the values were 15, 12, 33 and 14 μ g. per ml., respectively, for the control and supplemented groups. The values for arginine and valine were raised by addition of lysine alone, but not by lysine and methionine together.

In a further trial with an adequate control diet the lysine content of plasma was significantly reduced, from 108 to 78 μ g. per ml., by the addition of an excess of methionine to the diet, even though there was no adverse effect on the rate of growth. The arginine and valine contents were also reduced by this addition; that of tryptophan remained unchanged.—K. J. Carpenter.

3328

ROTHSTEIN, M. and MILLER, L. L. **The metabolism of L-lysine-6- C^{14} .** *J. Biol. Chem.*, 1954, **206**, 243–253. [Dept. Radiation Biol., Sch. Med. Dent., Univ. Rochester, N.Y.]

Lysine-6- ^{14}C was injected intraperitoneally into rats with large amounts of unlabelled suspected metabolites, and the metabolites were then isolated from the urine and examined for radioactivity.

Lysine could be converted to acetate and α -keto-glutarate, apparently by independent routes, to glutarate, and, in small amounts, to formate and glycine. When large amounts of unlabelled lysine were injected with the labelled, δ -aminovalerate was also labelled, and it is suggested that the conversion of lysine through the α -keto-acid to δ -aminovalerate was a secondary reaction.

In rats treated with phloridzin the glucose isolated from the urine was labelled predominantly in C atoms 3 and 4, with some activity in atoms 1 and 6 and a small amount in 2 and 5; acetoacetate was also labelled. The latter and the 3:4-labelled glucose were probably formed from glutaric acid and the other C atoms of the glucose from formate.

With similar techniques it was shown that α -aminoadipic acid-6- ^{14}C could be converted into glutarate, and that glutaric acid-1:5- ^{14}C could be converted into α -ketoglutarate and acetate in a way similar to the lysine conversion.

The findings were consistent with the reaction sequence lysine \rightarrow α -aminoadipate \rightarrow glutarate \rightarrow α -ketoglutarate and acetate.—C. Warner.

ARMSTRONG, M. D. **The utilization of L- and D-phenylalanine by the rat.** *J. Biol. Chem.*, 1953, **205**, 839–848. [Lab. Study Hereditary Metabol. Disorders, Coll. Med., Univ. Utah, Salt Lake City.]

Rats receiving from 0.5 to 4.0 per cent. D-, L- or DL-phenylalanine in the diet showed no ill effect. Growth rate, food consumption and food efficiency were greatest with the L- and least with the D-isomer; with D- and DL-phenylalanine growth was better at the 1 per cent. than at the 0.5 per cent. level. The response from 0.5 per cent. phenylalanine and 1 per cent. tyrosine was similar to that from 1.2 per cent. phenylalanine alone. In paired feeding experiments, growth and food efficiency were only slightly greater with L- than with D-phenylalanine; considered with the absence of phenylpyruvic acid from the urine of animals given D-phenylalanine at moderate levels, this suggested that there was little loss in inversion.

It is suggested that the lower consumption of diets containing the D-isomer is due to the animals' awareness in some way of an initial imbalance of amino-acids during the time taken for the D-isomer to be deaminated to the corresponding keto-acid in the kidney, transported to the liver and reaminated as the L-isomer; in support of this, phenylpyruvic acid was found to have an effect intermediate between those of D- and L-phenylalanine.—C. Warner.

3330

WRETLIND, K. A. J. **The availability of the isopropyl ester of L- and D-phenylalanine and 3, 6-dibenzyl-2, 5-diketopiperazine for growth in rats.** *Acta physiol. scand.*, 1954, **30**, 97–104. [Dept. Pharmacol., Karolinska Inst., Stockholm.]

The experimental diets were purified and contained all the amino-acids essential for the rat except phenylalanine, produced synthetically and given in the racemic form. Instead of phenylalanine the diets contained either 1.26 per cent. of the isopropyl ester of D- or L-phenylalanine or 2 per cent. of phenylalanine anhydride.

Both the esters were utilised as substitutes for phenylalanine, the L-ester giving slightly better growth than the D-. The anhydride gave results no better than the same diet without it.—D. Duncan.

CAVALLINI, D. and TENTORI, L. **Metaboliti del triptofano nelle urine di ratto studiati mediante cromatografia su carta.** [Metabolites of tryptophan in the urine of rats studied by paper chromatography.] *Boll. Soc. ital. Biol. sper.*, 1953, **29**, 497–501. [Ist. Chim. Biol., Univ. Rome.]

Male rats weighing about 80 g. were maintained on a purified basal diet. In alternate periods of 2 days L-tryptophan was added to the diet. The urine was collected and analysed chromatographically on paper. The spots were examined for ultraviolet fluorescence and by the ninhydrin reaction.

Before administration of tryptophan there was no fluorescent spot on the paper, and only one spot reacting with ninhydrin, due apparently to glycine. The urine collected 24 and 48 hr. after administration of tryptophan gave 8 fluorescent spots and 3 reacting with ninhydrin. Only 3 were identified. One substance was L-kynurenine, another probably acetylkynurenine, and the third kynurenic acid; anthranilic acid and 3-hydroxyanthranilic acid were not present.—E. M. Hume.

3332

DALGLIESCH, C. E. and TEKMAN, S. **The excretion of kynurenine and 3-hydroxykynurenine by man.** *Biochem. J.*, 1954, **56**, 458-463. [Postgrad. Med. Sch., London, W.12.]

In about 100 samples of human urine a positive diazo reaction was always associated with the presence of hydroxykynurenine, confirmed by paper chromatography.

Hydroxykynurenine was excreted by 13 out of 31 patients with fever, without any other apparent common factor. It was not excreted in disorders associated with weight loss but no fever. Two normal men who received 10 g. DL-tryptophan by mouth excreted in the next 24 hr. both D- and L-kynurenine, but no hydroxykynurenine.

The mechanism involved in the different patterns of excretion is discussed.—D. Duncan.

HARPER, A. E., MONSON, W. J., LITWACK, G., BENTON, D. A., WILLIAMS, J. N. (Jr.) and ELVEHJEM, C. A. **Effect of partial deficiency of threonine on enzyme activity and fat deposition in liver.** *Proc. Soc. Exp. Biol. Med.*, 1953, **84**, 414-417. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Rats were given for 2 weeks diets containing casein 9, sucrose 81.5, DL-methionine 0.3 and DL-tryptophan 0.1 per cent., maize oil, salts, choline and vitamins, with and without 0.36 per cent. threonine. Those on the threonine-deficient diet showed slow growth and greatly increased liver fat. The activities of the soluble liver enzymes xanthine oxidase and tyrosine oxidase and the endogenous oxygen uptake and CO₂ output were considerably less in homogenates from the deficient animals, and the activities of the mitochondrial enzymes succinic oxidase and choline oxidase were higher.

C. Warner.

3334

SCOTT, E. B. and SCHWARTZ, C. **Histopathology of amino acid deficiencies. 2. Threonine.** *Proc. Soc. Exp. Biol. Med.*, 1953, **84**, 271-276. [Dept. Anat., Sch. Med., Univ. S. Dakota, Vermillion.]

For part 1 see Abst. 5098, Vol. 21.

Male rats of mean bodyweight 100 g. were divided into 3 groups: 5 controls were fed to appetite on a complete synthetic diet containing 19 amino-acids; 9 others were given limited amounts of this ration on alternate days; the remaining 12 received to appetite a similar ration lacking threonine. After 45 days, all were killed except 2 deficient rats and 1 starved control, which were given a complete recovery diet for 45 days.

Rats in the control group were in every way normal and gained on the average 131 g. bodyweight. Deficient rats lost bodyweight, on the average 41 g. The testes were particularly atrophic, with no evidence of spermatogenesis, the tubules being composed principally of Sertoli cells resting on a basement membrane, sometimes with degenerating cells occupying the lumen. The interstitial cells were small and flat, and contained little cytoplasm. The epididymis was also atrophic, with sloughing seminiferous cells lying free within the lumen. The seminal vesicles and ventral prostates, also greatly atrophied, were in the castrate condition. The Golgi apparatus could not be demonstrated in the prostatic epithelium and there was a marked increase in prostatic interstitial tissue. The thyroid glands were small, but the follicular cells were normal in height, with the follicles themselves variable in size and colloid content. Of the pituitary only the anterior lobe was affected, the eosinophilic cells being conspicuously reduced in number, size and staining capacity, and gonadotropic basophilic cells positive to periodic acid Schiff being absent. There was atrophy but no change in structure of the adrenal glands and thymus, and considerable reduction in bone growth.

The rats given the recovery diet made uneventful and complete recoveries from the deficiency, and grew to the same average weight as the controls. The starved control rats lost on the average only 11 g. bodyweight, and although regression of some somatic tissues took place it was much less pronounced than that in the deficient animals. The pituitary was unaffected.

It is concluded that the primary effect of threonine deficiency was probably exerted on the eosinophilic and gonadotropic basophilic cells of the anterior lobe of the pituitary. In view of the normal histological appearance of the adrenal glands and the fact that only the so-called thyrotropic basophilic cells of the pituitary remained

undamaged, it is suggested that the hormone which activates the adrenal cortex has its source in these cells.—W. A. Greig.

HAVERMANN, H. and SCHARPENSEEL, H. Untersuchungen über das Verhalten des d, l-Methionins im Stoffwechsel des vollwertig und nicht vollwertig ernährten Schweins und Legehuhns. Bilanz- und Verteilungsstudien mit d, l-³⁵S-Methionin. [Behaviour of dl-methionine in the metabolism of pigs and laying hens on complete and incomplete diets. Balance and distribution studies with dl-³⁵S-methionine.] *Arch. Tierernährung*, 1953, **3**, 259-280. [Inst. Tierzucht, Rheinisch Friedrich-Wilhelms-Univ., Bonn.]

Two pigs, 14 weeks of age, were maintained in metabolism cages; one received a diet containing animal protein and the other only vegetable protein. After 14 days each received daily 0.1 per cent. ³⁵S-methionine in the food, and faeces and urine were collected, at first every 6 hr. and then every 12 hr. for 5½ days. In this time two-thirds of the ³⁵S was excreted in the urine, mainly in inorganic form; about 20 per cent., mainly in organic form, was recovered in the faeces and about 15 per cent. was deposited in the tissues. These results were independent of whether the ration contained animal or only vegetable protein.

Two laying fowls received a normal mixed diet containing animal protein, a second pair a diet containing only vegetable protein, and a third pair this diet with 0.35 per cent. Aurofac (containing 4 g. aureomycin and 4 mg. vitamin B₁₂ per kg.). After a preliminary period each bird received by mouth methionine containing 0.4 mC. ³⁵S. In all the birds 91 to 94.5 per cent. of ³⁵S was recovered in the excreta; of this about 84 per cent. was in organic and 16 per cent. in inorganic form. In the tissues the greatest radio-activity was in the liver of the birds of group 3, next in those of group 2 and least in those of the group receiving animal protein. In 6 days the total recovery of ³⁵S in the eggs represented from 0.28 to 0.34 per cent. of the intake, the highest content being in eggs laid on the second to fourth days.

Autoradiographs of frozen slices of livers from the pigs and hens showed uniform distribution of ³⁵S through the tissue.—W. Godden.

3336

FORBES, R. M. and VAUGHAN, L. Nitrogen balance of young albino rats force-fed methionine- or histidine-deficient diets. *J. Nutrition*, 1954, **52**, 25-37. [Div. Animal Nutrit., Univ. Illinois, Urbana.]

Young albino rats were forcibly fed. In the first experiment the diet contained, per cent., oxidised

casein 18, maize oil 18, sucrose 28.8, starch 28.8, minerals and vitamins. In the other 2 experiments the N source was a mixture of amino-acids, the carbohydrate was all starch and the maize oil was reduced to 5 per cent. All diets were low in or devoid of methionine. In experiment 2 histidine also was absent. In experiment 3 the animals were kept for a 7-day pre-period on a N-free diet in order to deplete body stores of protein.

The results of all 3 experiments, which are partly at variance with the results of Denton *et al.* (Abst. 5392, Vol. 20) and of Bothwell and Williams (Abst. 5111, Vol. 21), show that under the experimental conditions the amino-acid deficiencies resulted in reduced N retention due to increased urinary excretion. When the animals were depleted of protein before receiving the diet free of methionine, N balance remained negative.

W. Godden.

WINGO, W. J., SMITH, R. A. and WOOD, J. The metabolism of dl-methionine sulfone by the rat. *Arch. Biochem. Biophys.*, 1953, **47**, 307-313. [Dept. Biochem., M. D. Anderson Hosp. Cancer Res., Houston, Tex.]

Methionine sulphone labelled with ³⁵S was given by intraperitoneal injection to adult rats. Most of the radio-activity was recovered in the organic S fraction of the urine within 24 hr. Paper chromatograms of the urine showed radio-activity in 4 spots, 2 corresponding to unchanged sulphone and inorganic sulphate, respectively; but most of the activity was found in substances which could be extracted from the urine with boiling butanol and purified by chromatography on wood cellulose. Paper chromatograms after hydrolysis with 6N HCl showed spots corresponding to methionine sulphone and glutamic acid. Treatment of the unhydrolysed material with nitrous fumes failed to show free amino-groups. It is suggested that

N.A. and R., July 1954

the substance excreted was an open-chain peptide which became cyclic during extraction.

FATS AND OTHER LIPIDS

3342

FERNANDES, J. De vetresorptie bestudeerd bij een kind met chylothorax. [Fat absorption studied in a child with chylothorax.] *Thesis*, Univ. Leyden, 1953, pp. 76. English summary.

Literature is reviewed, with special reference to the discordant theories of Verzár and Frazer on fat absorption. The study described was of a child with congenital chylothorax, admitted to hospital at 22 months of age. Chyle was removed weekly for 8 months. A standard diet was given of a preparation of buttermilk, rice flour and sugar, potato, green vegetable, lean meat, banana, orange juice, tomato juice, vitamins A, D, B complex and C, and Fe. The fat to be investigated was given emulsified in the milk or with the other foods. Total fatty acids and saturated fatty acids individually were estimated by Boldingh's methods (Abst. 46, Vol. 20) in the food, faeces and chyle weekly and once in blood. The child was in good health except for a short time on low-fat diet when he had an enteritic infection with steatorrhoea. The following fats were given, one at a time: butter, margarine, coconut fat and a synthetic fat consisting of 38 per cent. caprylic acid in olive oil, for the short-chain fatty acids; cocoa fat for fatty acids C₁₆ and C₁₈; a synthetic fat with hardened herring oil for fatty acids C₂₀ and C₂₂; sunflower seed oil and linseed oil for linoleic and linolenic acids; rape oil for erucic acid; olive oil for oleic acid, C₁₈ mono-ethylenic, *cis*-isomer, and olive oil with elaidic acid for elaidic acid, C₁₈ mono-ethylenic, *trans*-isomer.

Vol. 24, No. 3

A table gives the comparison of chyle and food fat for each fat and the results are summarised in one diagram to show that the composition of the chyle changed from one fat to another but was approximately constant for a given fat. Saturated fatty acids C₄ and C₆ were not found in chyle, and C₈ only when caprylic acid was given in excess in olive oil. The percentage of fatty acids C₁₀, C₁₂, C₁₄ and C₁₆ recovered in chyle increased with the length of the carbon chain, and C₁₈ appeared to be better absorbed than C₁₆ if it was present only in small amount, but less well if present in large amount. The behaviour of C₂₀ and C₂₂ appeared to be similar but is not established. Oleic and elaidic acids were equally well absorbed. Unsaturated acids were uniformly well absorbed.

These results are explicable only if some hydrolysis of food fat occurs, *e.g.*, of butter, margarine and coconut fat; others may be absorbed without hydrolysis, *e.g.*, olive oil, sunflower seed oil, linseed oil and rape oil. Cocoa fat was poorly absorbed. The mechanics of absorption are not explained by these observations.—I. Leitch.

CULLEN, C. F. and SWANK, R. L. **Intravascular aggregation and adhesiveness of the blood elements associated with alimentary lipemia and injections of large molecular substances.** *Circulation*, 1954, **9**, 335-346. [Dept. Neurol., McGill Univ., Montreal.] Spanish summary.

Studies on hamsters showed that after a high fat meal of 2 to 15 g. per kg. bodyweight, changes occurred in the circulation which appeared after the peak of lipaemia was passed and developed to their maximum as the lipaemia cleared. There was increased adhesiveness and aggregation of red blood cells, and occasional clumping of platelets; the rate of circulation fell and at times there was complete cessation of blood flow. The changes were reversible, and after complete clearing of the lipaemia the circulation resumed a normal appearance. Similar circulatory changes were produced by injection of solutions of substances of large molecular weight, such as dextran, egg albumin and thromboplastin. When the circulatory changes were severe, as in all the hamsters which received dextran, pathological changes were found in the blood-brain barrier. The significance of these findings and their possible relation to multiple sclerosis and vascular thrombosis are discussed. A coloured cinephotomicrograph has been prepared showing the circulatory changes.

HEYMAN, W., MATTHEWS, L. W., LEMM, J., OLYNYK, P., SALEHAR, M. and GILKEY, C. **Fat metabolism in nephrotic hyperlipemia.** *Metabolism*, 1954, **3**, 27-31. [Dept. Paediat., Sch. Med., W. Reserve Univ., Cleveland, Ohio.]

Sixteen rats with nephrosis and high blood lipids and 15 control rats were given an intravenous injection of fat emulsion containing ^{14}C -labelled trilaurin. The fate of the administered fat was studied by collecting the expired CO_2 in a respirometer and estimating its ^{14}C content. Clearance of ^{14}C -trilaurin from the bloodstream of 5 nephrotic and 5 control rats was studied by direct counting of the radio-activity of dried blood samples taken

at intervals of 0.5, 1, 2, 3, 4, 6 and 8 hr. after the injection. The blood clearance of intravenously injected coconut oil emulsion in 22 nephrotic and 16 control rats was studied by direct estimation of total plasma lipids at intervals.

The specific activity of the respired CO_2 was low in 5 and normal in 11 nephrotic animals. Though these 5 rats failed to metabolise trilaurin normally, no correlation with the degree of lipaemia could be established and the finding is thought to be of doubtful significance. The blood clearance of radio-active trilaurin and of coconut oil proceeded at the same rate in nephrotic and normal animals.

It is concluded that the high blood lipids in nephrosis may be due to increased fat mobilisation rather than to faulty deposition or utilisation of lipids.—G. A. Garton.

3347

CUNNINGHAM, H. M. and LOOSLI, J. K. **The effect of fat-free diets on lambs and goats.** *J. Animal Sci.*, 1954, **13**, 265-273. [Cornell Univ., Ithaca, N.Y.]

Four weanling lambs fed on a fat-free diet showed no sign of essential fatty acid deficiency. Traces of linoleic and linolenic acids were present in the rumen, but their concentration declined as the experiment progressed. No arachidonic acid was detected in the rumen contents. As the lambs lost weight, it is possible that tissue stores were sufficient to prevent fat deficiency. No bacteria isolated from the rumen of a cow on a natural diet synthesised essential fatty acids when grown on fat-free media.

In the second trial 8 two-day-old lambs and 7 two-day-old goats were used. The lambs on fat-free synthetic milk died within 7 weeks, but those on the same milk with 2 per cent. lard were reared successfully. The kids on fat-free milk died within 3 weeks, those on the milk plus 0.25 per cent. lard or 0.36 per cent. linoleic acid survived. Kids on a diet containing 0.05 per cent. lard died.

MEAD, J. F., STEINBERG, G. and HOWTON, D. R. **Metabolism of essential fatty acids. Incorporation of acetate into arachidonic acid.** *J. Biol. Chem.*, 1953, **205**, 683-689. [Dept. Physiol. Chem., Sch. Med., Univ. California, Los Angeles.]

Seventeen weanling rats were given 3 daily intraperitoneal injections of Na $1\text{-}^{14}\text{C}$ -acetate and were killed on the 4th day. Lipids were extracted

N.A. and R., July 1954

from the pooled kidneys, hearts, livers and abdominal fat deposits and then saponified to yield fatty acids, which were separated by Pb salt fractionation. Radio-activity of the fractions was estimated.

Acetate was not incorporated into linoleic acid to any appreciable extent, in confirmation of the work of Bernhard and Schoenheimer (Abst. 3565, Vol. 10). The arachidonic acid contained ^{14}C almost exclusively in the carboxyl group, showing that it was formed from a C_{18} precursor probably derived from linoleic acid.—G. A. Garton.

3350

THOMASSON, H. J. **Stearolic acid, an essential fatty acid?** *Nature*, 1954, **173**, 452. [Unilever Res. Lab., Zwijndrecht, Netherlands.]

Stearolic acid, Δ^8 -octadecynoic acid-1, did not improve survival time, tail lesions or growth of rats depleted of essential fatty acids.

KLEIN, P. D. and JOHNSON, R. M. **Changes with age in the unsaturated fatty acids content of subcellular particles of rat livers.** *Arch. Biochem. Biophys.*, 1954, **48**, 172-177. [Detroit Inst. Cancer Res., Mich.]

Male albino rats were fed from weaning on a commercial diet and groups of from 4 to 6 animals were killed at intervals between 1 and 16 months of age. Other rats were fed from weaning on another commercial diet containing more linoleic and linolenic acids than the first; from 4 to 6 animals were killed at ages between 6 and 20 months. The livers were removed and homogenised before fractionation into mitochondria, microsomes and a slightly sedimentable layer. Di-, tri-, tetra- and pentaenoic acids were estimated in each particulate fraction by the method of Herb and Riemenschneider (Abst. 66, Vol. 24).

No change occurred in polyunsaturated fatty acid concentration in the 3 particulate fractions up to the age of 11 months. After this the group which received the diet lower in unsaturated fatty acids showed higher concentrations of trienoic acids in the cytoplasmic particles, and a decline in pentaenoic acid. No change was found in preparations from animals which received the diet higher in unsaturated fatty acids.—G. A. Garton.

MAYER, J. and ZIGHERA, C. Y. **The multiple etiology of obesity: production of two types of obesity in littermate mice.** *Science*, 1954, **119**, 96-97. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

Mice with obesity of genetic origin had high blood sugar levels which were raised higher by treatment with growth hormone. In obesity

induced by injection of gold thioglucose (see Waxler and Boecher, *Amer. J. Physiol.*, 1952, **162**, 428), even in littermates of genetically obese mice, the blood sugar was normal before and after treatment with growth hormone.

One unit of insulin produced convulsions in mice treated with gold thioglucose, but genetically obese mice were resistant.—D. Harvey.

3353

MAYER, J. and JONES, A. K. **Hypercholesteremia in the hereditary obese-hyperglycemic syndrome of mice.** *Amer. J. Physiol.*, 1953, **175**, 339-342. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

The obese mice were 4 to 5 months old and weighed from 45 to 60 g., and each was caged with a normal mouse weighing 20 to 30 g. They were fed on stock pellets or on one of the following diets: high-carbohydrate, containing sucrose 80.7, casein 10, maize oil 3, cod liver oil 2, salt mixture 4, cystine 0.2 and choline 0.1 per cent.; high-protein, with casein increased to 60 and sucrose reduced to 30.7 per cent.; and high-fat, containing lard 46, maize oil 5.9, cod liver oil 2, casein 39.4, salt mixture 6.3, cystine 0.25 and choline 0.15 per cent. B vitamins, menadione and α -tocopherol were supplied to all mice.

On stock diet the mean blood sugar in normal mice was 109 mg. per 100 ml., standard deviation ± 23 , and in obese mice 180 ± 77 . Serum cholesterol was 74 ± 14 and 134 ± 21 mg. per 100 ml., respectively.

On the high-carbohydrate diet the weight of obese and normal mice increased; in obese animals blood sugar and cholesterol values rose, the latter to 165 ± 30 , but in normals it fell to 55 ± 7 mg. per 100 ml. On the high-protein diet obese animals gained, but controls lost weight; blood sugar in obese mice rose from 131 ± 15 to 277 ± 135 mg. and cholesterol to 177 mg., but in normals cholesterol values were halved, falling to 34 ± 5 mg. per 100 ml. The high-fat diet produced a poor appearance in obese mice and one died; blood sugar rose in controls and fell in obese animals, and cholesterol was unchanged. Fasting for 18 to 20 hr. caused a sharp fall in the blood sugar of obese mice from 278 ± 29 to 114 ± 36 and a significant rise in serum cholesterol to 170 ± 7 mg. per 100 ml., but controls showed a slight fall in blood sugar and no change in cholesterol.

Growth hormone, 1 mg. daily, greatly raised blood sugar in obese mice and slightly raised serum cholesterol in obese and control animals. Thyroxine, 50 μg . daily, halved serum cholesterol in both groups, and obese mice lost weight. Adrenocorticotrophic hormone and diethylstilboestrol had little or no effect.

The high serum cholesterol values are considered to be an essential part of the hereditary syndrome of obesity and diabetes.—D. Duncan.

HARPER, A. E., MONSON, W. J., BENTON, D. A., WINJE, M. E. and ELVEHJEM, C. A. **Factors other than choline which affect the deposition of liver fat.** *J. Biol. Chem.*, 1954, 206, 151-158. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Groups of 6 weanling rats were fed to appetite. The basal diet consisted of sucrose 81.6, casein 9.0,

DL-methionine 0.3, maize oil 5, salts 4 and choline chloride 0.13 per cent., with vitamins. Supplements, replacing an equal weight of sucrose, included gelatine, DL-threonine, DL-tryptophan, glycine, serine, choline, betaine, cystine, mixtures of ketogenic amino-acids, thiocetic acid, pantethine, maize oil and butterfat, individually or in combination. After 2 weeks the animals were killed and liver fat was estimated.

The results show that the amount of liver fat in young rats receiving choline depends on the interaction of several substances, though threonine was found to be particularly effective in reducing fat deposition. Tryptophan reduced the effectiveness of threonine. Although betaine, glycine and serine were each only partly effective in preventing deposition of liver fat, combinations of these amino-acids were almost as effective as threonine. Threonine was not effective in the absence of choline. Fat did not accumulate progressively in the livers of animals which received increasing amounts of dietary fat.

It is suggested that threonine, and probably other essential amino-acids, may be required for the formation of an enzyme or enzymes necessary for normal liver metabolism.—G. A. Garton.

3361

DUCHESNE, D. D. and BERNARD, R. **Further studies on lipotropism in the domestic duck (White Pekin).** *Canad. J. Med. Sci.*, 1953, 31, 474-484. [Dept. Biol., Laval Univ., Quebec.]

Supplementing a choline-free diet containing 10 per cent. casein with 0.5 per cent. methionine raised the level of liver lipids in ducklings, but the supplement had no effect when the diet contained 18 per cent. casein, and with 28 per cent. casein it was lipotropic. When a purified soya bean protein, low in methionine, was used in place of casein, at levels of 12, 21.7 and 27.9 per cent., there was no difference in liver lipids, but methionine was lipotropic at all and especially at the higher protein levels. It was concluded that soya bean protein is not lipotropic, that casein is lipotropic, and that the lipotropic activity of methionine is closely related to the quality and quantity of the protein in the diet.

Diets high in fat produced high levels of liver lipids, but were less lipogenic than diets rich in carbohydrates. Choline had no lipotropic effect with diets containing 22 to 42 per cent. fat, but was strongly lipotropic with fat-free diet, even one supplemented with 1 per cent. cholesterol. Inositol was also lipotropic under these conditions, though less so than choline. The actions of both choline and inositol were evident primarily on the glyceride fraction, and were synergistic.

HELLMAN, L., ROSENFELD, R. S. and GALLAGHER, T. F. **Cholesterol synthesis from C¹⁴-acetate in man.** *J. Clin. Invest.*, 1954, **33**, 142-149. [Div. Phys. Biophys., Sloan-Kettering Inst. Cancer Res., New York 21.]

Acetate labelled with ¹⁴C was given by mouth to 6 hospital patients with limited expectancy of life. Blood samples were taken at intervals up to 43 days afterwards for estimation of the ¹⁴C content of the free and ester cholesterol in the plasma.

The highest specific activity of free cholesterol was found within 8 hr., followed by a gradual decline. The maximum specific activity of ester cholesterol was not reached until 2 days after the labelled acetate was given, and then it declined at a rate similar to that of free cholesterol. A minimum of 3 per cent. of the acetate was incorporated into plasma cholesterol.—G. A. Garton.

3365

SWELL, L., FLICK, D. F., FIELD, H. (Jr.) and TREADWELL, C. R. **Influence of dietary bile salts on blood cholesterol levels.** *Proc. Soc. Exp. Biol. Med.*, 1953, **84**, 428-431. [Veterans Admin. Centre, Martinsburg, W. Va.]

After being reared on stock diet, 45 rats in 7 groups received to appetite a basal diet with percentage composition casein 20, starch 23, glucose 23, olive oil 25, salt mixture 5, ruffex 2 and cholesterol 2, with crystalline vitamins. Individual groups received for 21 days 1 per cent. cholate, taurocholate, deoxycholate or dehydrocholate and one group received in succession dehydrocholate

for 7 days, taurocholate 7 days and dehydrocholate 5 days.

Total blood cholesterol increased in all groups after a week; it was not significantly higher with dehydrocholate than without bile salt, but cholate, taurocholate and deoxycholate gave increases 41.1, 36.9 and 16.5 per cent. greater, respectively, than the diet without bile salt. When the bile salts were given in succession dehydrocholate at first had no effect, but after the blood cholesterol was raised by taurocholate it was reduced by dehydrocholate. No toxic effect was detected.

The relation of bile salts to blood cholesterol is discussed.—D. Duncan.

3366

SHERBER, D. A. and LEVITES, M. M. **Hypercholesterolemia: effect on cholesterol metabolism of a polysorbate 80-choline-inositol complex (Monichol).** *J. Amer. Med. Assoc.*, 1953, **152**, 682-686. [Metabol. Res. Lab., Fordham Hosp., New York.]

Of 960 patients admitted consecutively to the medical services of Fordham Hospital, 131 (13.7 per cent.) had serum cholesterol values above 300 mg. per 100 ml., and of these 91 had cardiovascular disease and 27 diabetes. The incidence of high blood cholesterol values between ages 30 and 80 rose with age, and between 40 and 70 years high blood cholesterol was commoner in women than in men.

Preliminary trials showed that neither a 30 per cent. aqueous solution of polysorbate 80 nor a mixture of choline, inositol and methionine was effective in reducing serum cholesterol, but that significant reduction was obtained with a mixture containing 500 mg. polysorbate 80, 500 mg. choline dihydrogen citrate and 250 mg. inositol per 5 ml. In a more extended trial with 16 patients, 15 responded to 20 ml. daily of this mixture given in 4 doses. There was a simultaneous rise in urinary cholesterol.

It is suggested that the mechanism of reduction of serum cholesterol is related to adrenal cortical function. More extensive studies are in progress. [Some of the tables are not reproduced but are given in authors' reprints.]—W. M. Deans.

3367

FILLIOS, L. C. and MANN, G. V. **Influence of sulfur amino-acid deficiency on cholesterol metabolism.** *Metabolism*, 1954, **3**, 16-26. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

Groups of mice and rats were fed for several weeks on diets containing soya bean protein or casein with and without the addition of cholesterol. For some the soya bean protein diet was supplemented with DL-methionine. Blood cholesterol

was estimated from time to time, and at the end of the rat experiments their liver lipids were fractionated for estimation of phospholipins and total and free cholesterol.

The experimental diets which included cholesterol caused a rise of serum cholesterol, especially in the animals given soya bean protein; the high serum cholesterol fell when DL-methionine also was included in the diet. Animals given soya bean protein without cholesterol lost appetite, and it was not improved by methionine. No consistent relation between liver and serum cholesterol was found in the rats with high serum cholesterol. No arteriosclerosis was seen in these short experiments.

FRANTZ, I. D. (Jr.), SCHNEIDER, H. S. and HINKELMAN, B. T. Suppression of hepatic cholesterol synthesis in the rat by cholesterol feeding. *J. Biol. Chem.*, 1954, **206**, 465-469. [Cardiovascular Res. Lab., Dept. Med., Harvard Med. Sch., Boston, Mass.]

Male rats were used, some of which had previously had their thyroid glands damaged by the administration of radio-active I. Groups of these animals were fed on a diet of Purina chow with or without the addition of 1 per cent. cholesterol, and were killed at intervals up to 5 weeks. Blood and liver cholesterol were estimated and liver slices were incubated for 3 hr. with ^{14}C -carboxyl-labelled acetate. Cholesterol was isolated from the incubation medium and its radio-activity was measured.

Serum cholesterol values of rats with damaged thyroids were slightly higher than those of normal animals, even on the diet without cholesterol. When cholesterol was included in the diet, the rise in serum cholesterol was greater than in the animals with normal thyroids. Liver cholesterol rose to the same extent after the administration of cholesterol in both normal rats and those with damaged thyroids.

Formation of cholesterol from acetate was inhibited to at least as great an extent in animals which had received radio-active I as in normal rats.

G. A. Garton.

3370

ROSENMAN, R. H., BYERS, S. O. and FRIEDMAN, M. The effect of dihydrocholesterol on the absorption of cholesterol by the rat. *Circulation Res.*, 1954, **2**, 45-47. [Harold Brunn Inst., Mount Zion Hosp., San Francisco, Calif.]

Male rats with thoracic duct cannulae were given by stomach tube 100 mg. cholesterol with or without 100 mg. dihydrocholesterol. When dihydrocholesterol was given with the cholesterol the amount of cholesterol found in the lymph in the subsequent 24 hr. was only 63 per cent. of that found when cholesterol was given alone.

Rats were fed on a stock diet to which were added 2 per cent. cholesterol and 1 per cent. cholic acid to induce a high blood cholesterol level; 1 group received also 2 per cent. dihydrocholesterol. Blood samples were taken for total and ester cholesterol estimation at intervals of 2 weeks during 2 months. The addition of dihydrocholesterol slowed down the development of high blood cholesterol and reduced its intensity.

G. A. Garton.

3371

HERNANDEZ, H. H., CHAIKOFF, I. L., DAUBEN, W. G. and ABRAHAM, S. The absorption of C^{14} -labeled epicholesterol in the rat. *J. Biol. Chem.*, 1954, **206**, 757-765. [Dept. Physiol., Sch. Med., Univ. California, Berkeley.]

Twelve rats had cannulae in the thoracic lymph ducts. Of these, 6 received by stomach tube 1 mg. ^{14}C -labelled cholesterol dissolved in 0.25 ml. maize oil and the other 6 received 1 mg. ^{14}C -labelled epicholesterol, the 3- α -hydroxy-isomer of cholesterol. Intestinal lymph was then collected at intervals for estimation of free and combined sterol and measurement of their radio-activity.

Cholesterol was more rapidly absorbed than epicholesterol and ^{14}C recoveries from the lymph of rats given cholesterol were about twice those found in rats given epicholesterol. About 50 per cent. of the cholesterol recovered was esterified, but almost no epicholesterol was found in ester combination. Esterification may be responsible for the difference observed in the rates of absorption of the 2 stereo-isomers.—G. A. Garton.

3372

YOSHIHARA, M. [Biochemical studies on the compound lipids. 11. On the rat's organ plasmalogen in the various dietary fatty livers.] *Sapporo Med. J.*, 1953, **4**, 75-78. [Dept. Biochem., Sapporo Univ. Med.] In Japanese: English summary.

Fatty livers were produced in rats by low-protein and high-fat, high-cholesterol or raw liver diets. Neutral fat was from 3 to 11 times the normal, but only in the animals receiving raw liver was the plasmalogen content increased, and that tenfold. (From summary.)—D. Harvey.

3373

McKIBBIN, J. M. and BREWER, D. W. Effect of inositol feeding on inositol phosphatides and

N.A. and R., July 1954

other lipids of human blood plasma. *Proc. Soc. Exp. Biol. Med.*, 1953, **84**, 386-388. [Dept. Biochem., Coll. Med. State Univ. New York, Syracuse.]

Thirteen patients aged from 34 to 68 years showed different degrees of high-tone deafness, supposed to be associated with arteriosclerosis. Blood samples were taken before and after inositol treatment, 1 g. inositol being given by mouth 3 times daily for from 1 to 12 months.

No significant change occurred in plasma inositol phosphatides, and increases in total and free cholesterol and total phospholipins were of doubtful statistical significance. There was an apparent decrease in neutral fat, especially in patients with cholesterol values above 200 mg. per 100 ml.

D. Duncan.

3374

JONES, R. J., KRAFT, S. C., HUFFMAN, S., BALTER, E. L. and GORDON, R. B. **The effect of a cholesterol-free brain fraction against diet-induced atherosclerosis.** *Circulation Res.*, 1953, **1**, 530-533. [Dept. Med., Univ. Chicago, Ill.]

Four groups of twelve 10-week old cockerels were given chicken mash mixed with 8 per cent. cottonseed oil and 1 per cent. cholesterol, alone or with a crude lipid-poor brain powder, such as was used in earlier experiments (Abst. 4676, Vol. 23), added at the rate of 5, 10 or 15 g. per 100 g. After 5 weeks the birds were killed and evidence of arteriosclerosis was assessed macroscopically by the system of Dauber *et al.* (Abst. 3739, Vol. 19), as well as by microscopic examination.

Grossly and microscopically the lesions were progressively less severe as the supplement of brain powder increased in amount. The powder's active component is thought to be a cerebroside, but its high protein content may also affect the

serum cholesterol or the occurrence of arteriosclerosis.—D. Harvey.

3375

COOK, D. L., MILLS, L. M. and GREEN, D. M. **The mechanism of alloxan protection in experimental atherosclerosis.** *J. Exp. Med.*, 1954, **99**, 119-124. [Div. Biol. Res., G. D. Searle and Co., Chicago, Ill.]

Of 3 groups of rabbits, one consisted of controls, the second of animals rendered diabetic by injections of alloxan and the third of rabbits which had been given alloxan but in which the pancreas had, during the period of alloxan absorption, been occluded from the circulation and protected from its action. Several weeks later all groups were given to appetite Rockland rabbit ration with 1 per cent. cholesterol added. Food consumption was measured and at the end of 8 weeks the animals were killed.

When compared with the other groups the diabetic animals were found to have consumed significantly greater quantities of food and to have significantly higher values for serum cholesterol and lipoproteins of S₁ 5 to 9 and 16 to 30 classes; the degree of arteriosclerosis was not significantly different. The alloxan-protected rabbits were similar to the controls. In its effect on tissues other than the pancreas alloxan gives no protection against arteriosclerosis produced by cholesterol.—D. Harvey.

CALCIUM AND PHOSPHORUS

3380

BREWER, W. D., CEDERQUIST, D. C., COLE, B., TOBEY, H., OHLSON, M. A. and STRINGER, C. J. **Calcium and phosphorus metabolism of women with active tuberculosis.** *J. Amer. Dietetic Assoc.*, 1954, **30**, 21-24. [Dept. Foods Nutrit., Michigan State Coll., East Lansing.]

The 6 women chose their diets from the foods served to them in hospital. After 2 weeks' observation on customary hospital diet their milk intake was restricted to 300 g. daily for 2 periods and then increased to 1200 g. daily for 2 periods. Each period consisted of 14 days of dietary adjustment followed by a 7-day balance study.

A supplement of 5 mg. riboflavin given during periods 2 and 4 had no effect on Ca and P retentions. From the regression of Ca intake on retention, equilibrium was predicted at an intake of 1.22 g., which is higher than is usually predicted for healthy women. The intake of P required for equilibrium was predicted to be 1.38 g. per day, which is not significantly different from values for healthy women reported in the literature.

F. C. Aitken.

3381

HANSARD, S. L., COMAR, C. L. and PLUMLEE, M. P. **The effects of age upon calcium utilization and maintenance requirements in the bovine.** *J. Animal Sci.*, 1954, **13**, 25-36. [Univ. Tennessee-Atomic Energy Commission Agric. Res. Program, Oak Ridge.]

Thirty-four Hereford cattle were used, in age from 10 days to 190 months. The calves aged 10 and 30 days received fresh milk and the older animals balanced rations for 2 to 6 months before the balance trials. Chemical and radio-active balance studies were made for 7 days after each received a single dose of ^{45}Ca by mouth or intravenously.

The percentage of total Ca intake excreted in the faeces increased from 7.2 ± 3 at 10 days to 82 ± 12 at 2 years, 103 ± 10 in mature and 128 ± 14 in aged cattle. Even when the old cows received large supplements of Ca they remained in negative balance. By the method reported earlier (Title 3816, Vol. 21) it was estimated that true absorption was 99 per cent. of the intake at 10 days, 34 per cent. in adult and 22 per cent. in aged cows. Retention was 91, 28 and 16 per cent., respectively, and of the faecal Ca 3, 33 and 45 per cent. came from the body stores. The difference between apparent and true digestibility increased with age. Maintenance requirements, based on the endogenous faecal Ca and the true digestibility, were estimated as 0.55 g. per 100 lb. bodyweight daily at 10 days and 2.0 g. from 6 months to maturity.

LOFGREEN, G. P. and KLEIBER, M. **Further studies on the availability of phosphorus in alfalfa hay.** *J. Animal Sci.*, 1954, **13**, 258-264. [Dept. Animal Husb., Univ. California, Davis.]

For method see Abst. 5144, Vol. 23. Balance trials were made with 4 yearling wethers fed on the same alfalfa hay as in the previous experiment. Each sheep received a single subcutaneous injection of sodium phosphate containing 4.5 mC. ^{32}P .

The peak concentration of ^{32}P , expressed as mC. ^{32}P per g. total P, occurred in the plasma on the first day and in the faeces one day later. The specific activity of the urine was not a true measure of plasma concentration. From the fourth day onwards there was a close correlation between plasma and faecal activity and from the seventh to the thirteenth day the relation was linear. The metabolic P content of the faeces could be estimated from the activity of blood samples on the seventh and thirteenth days and of faeces from the eighth to the fourteenth day.

In the hay used the average true digestibility of P was 94 per cent. and the average metabolic P content of the faeces was 92 per cent.—D. Duncan.

GILLIS, M. B., NORRIS, L. C. and HEUSER, G. F. **Studies on the biological value of inorganic phosphates.** *J. Nutrition*, 1954, **52**, 115-125. [Agric. Exp. Stat., Cornell Univ., Ithaca, N.Y.]

Chicks were fed from day-old to 4 weeks on a purified diet low in P and Ca. A specially prepared sample of β -tricalcium phosphate or other supplement was added to give a total of 0.20, 0.25, 0.30 and 0.35 per cent. P in the diet. The ash content of the fat-free tibia was estimated at 4 weeks. The Ca:P ratio was adjusted to 2:1 by adding calcium carbonate. The biological value or availability of the phosphate supplements was compared with that of β -tricalcium phosphate.

Bone products, defluorinated rock phosphate and feed grade dicalcium phosphates all gave high values, raw rock phosphates gave moderate to low values, and most pyrophosphates and metaphosphates were unavailable to the animal.

NOZAKI, H., HORII, S., TAKEI, Y., HASHIZUME, T., MORIMOTO, H. and KAISHIO, Y. [On the accumulation process of phosphorus compounds in hen's egg.] *Bull. Nat. Inst. Agric. Sci., Chiba, Japan [G]*, 1953, No. 7, 161-168. In Japanese: English summary.

Two laying hens received 75 μC . ^{32}P as phosphate by mouth and the first 7 eggs collected from each hen were analysed. Radio-activity, mainly in the shell, was detected in the first eggs laid, within 26 hr. In the second eggs laid, after 72 to 76 hr., the total activity had increased about tenfold and was mostly in the yolk. Activity in the yolk reached its peak in the fourth eggs, but was

still appreciable in the seventh eggs laid after 9 to 10 days. Of the ^{32}P administered 6.3 to 7.8 per cent. was recovered in the 7 eggs produced in 10 days and of this 90 per cent. was in the yolks, mostly in the phosphatide and protein fractions.

Five eggs were collected over 7 days from each of 2 other hens after a similar dose of ^{32}P by mouth and the yolks of the eggs were submitted to more detailed analysis. Maximum activity in the yolk was found in the fourth eggs and ^{32}P appeared earlier in the protein than in the fat. The percentages of the total ^{32}P activity found in the yolk as lipoprotein were from 41.18 in the first egg to 76.16 in the fourth, as combined phosphatide from 22.56 in the first egg to 0.40 in the fifth, as cephalin from 2.01 in the second egg to 8.34 in the fourth and as lecithin from 4.53 in the second egg to 33.12 in the fifth. (From summary.)

BLAINEY, J. D., COOKE, W. T., QUINTON, A. and SCOTT, K. W. **The measurement of total exchangeable potassium in man, with particular reference to patients with steatorrhoea.** *Clin. Sci.*, 1954, **13**, 165-176. [Dept. Med., Univ. Birmingham.]

The technique of isotope dilution with radio-active K and the method of calculation of the total exchangeable K are described and the technical errors are discussed.

The subjects were 24 controls, 12 patients with steatorrhoea and 11 in whom electrolyte depletion was expected. Equilibrium between the radio-active isotope and the ^{39}K of the body was reached in the control subjects in about 18 hr. after the test dose of radio-active K, but in the patients with steatorrhoea not for 30 hr. In the control group 17 males had a mean exchangeable K of 3016 m. equiv., ± 191 (S.E.), and 7 females one of 2411 ± 141 . In contrast the 6 male and 6 female patients with steatorrhoea had mean exchangeable K values of 1940 ± 242 and 1355 ± 80 m. equiv.; these values are significantly lower than those of the controls, but when expressed in terms of exchangeable K per kg. bodyweight or per sq. m.

body surface there is no significant difference. Administration of K supplements caused K retention in patients with steatorrhoea.

The results are considered to indicate a state of K depletion in steatorrhoea.—L. Wills.

3390

FOURMAN, P. **Depletion of potassium induced in man with an exchange resin.** *Clin. Sci.*, 1954, **13**, 93-110. [Nuffield Dept. Clin. Med., Oxford.]

The clinical and biochemical findings when K deficiency was induced in 3 experiments on 2 normal subjects are described. The loss of K induced by the ammonium form of the resin in 2 experiments was 28 per cent. of total body K; this was greater than the loss induced by the hydrogen form. Loss of water and phosphate from cells was less than K loss. While the resin was being given Na, Mg and Ca were not retained in place of K. Loss of K was accompanied by extracellular acidosis and a deficit of N.

Severe K depletion caused the subjects to become mentally confused and they suffered from weakness, anorexia and apathy.—F. C. Aitken.

ROSENMAN, R. H., FREED, S. C., ST. GEORGE, S. and SMITH, M. K. **Effect of varying dietary potassium upon the blood pressure of hypertensive rats.** *Amer. J. Physiol.*, 1953, **175**, 386-388. [Harold Brunn Inst., Mount Zion Hosp., San Francisco, Calif.]

For earlier work see Abst. 729, Vol. 21.

The right kidney was removed from male rats aged 4 to 5 weeks, and a figure-of-eight ligature was placed around the left kidney. After 6 weeks 76 rats were selected as having systolic blood pressures consistently above 140 mm. Hg. A group of 47 of these received a diet providing only 0.006 per cent. K, 11 others received the same diet with KCl to give 0.03 per cent. K, and 18 the same diet with a K content equal to that of the stock ration, 0.3 per cent. Blood pressures were recorded weekly for 8 weeks, after which most of the rats were killed for estimation of K in the serum, heart and skeletal muscle.

Only the severely depleted rats lost weight. The average blood pressure in this group was initially 166 mm. Hg, range 140 to 220, and finally 129 mm., range 90 to 160. The corresponding averages in the slightly depleted group were 170 and 146, and in the control group the average rose from 164 to 184 mm.

At the end of the experiment the average serum K was 3.1 m. equiv. per litre in the first group, and 4.6 and 4.5 in the second and control groups, respectively. Similarly, myocardial K was reduced to 79, range 57 to 95, in the first group, but

not significantly reduced in slight depletion, at 84, 80 to 89, compared with the control level of 87, 81 to 96. In skeletal muscle, K concentration was reduced in both depleted groups to about the same extent.—D. Duncan.

GREEN, D. M., JOHNSON, A. D., BRIDGES, W. C. and LEHMANN, J. H. **Stages of salt exchange in essential hypertension.** *Circulation*, 1954, **9**, 416-424. [Sch. Med., Univ. S. California, Los Angeles.] Spanish summary.

Observations were made of the salt and water excretion of 79 patients on self-regulated intakes of these substances. Patients with high blood pressure could be divided into those with high and those with normal Na excretion. The former were characterised by high output of salt and water, both under basal conditions and under saline or mannitol loads, an increased appetite for salt and a nearly normal glomerular filtration rate in spite of reduced plasma flow. The second group had a relatively normal output of salt and water, both under basal conditions and under load, a normal appetite for salt, and a low glomerular filtration rate and renal plasma flow. The mean cardiac output did not differ significantly in the 2 groups. The findings are interpreted to indicate that high salt excretion represents an early stage of hypertensive disease and normal salt excretion a later stage. The patterns of salt exchange in human hypertension resemble those in experimental corticoid and renal hypertension.

3393

WILHELMJ, C. M., MEYERS, V. W., MILANI, D. P. and MCCARTHY, H. H. **Effect of sodium chloride upon the blood pressure of normal dogs when administered during dietary stress.** *Amer. J. Physiol.*, 1954, **176**, 86-88. [Dept. Physiol., Sch. Med., Creighton Univ., Omaha, Nebr.]

Stress was produced in 3 dogs by diets rich in carbohydrate without or with salt in amounts of 25, 40 or 50 g. daily given after prolonged fasting. Such re-feeding without salt caused a large increase in systolic pressure but the addition of salt later produced negligible changes. When the diet and salt were given simultaneously the effect in increasing systolic pressure was similar to that found by Wilhelmj *et al.* (Title 3827, Vol. 21) with unfasted dogs. Diastolic pressure was usually unaffected.

Substitution of isocaloric amounts of raw horse meat in the carbohydrate diet caused a reduction in the systolic pressure (Title 3272, Vol. 24) unaffected by the presence or absence of salt.

RICHTER, C. P. and MOSIER, H. D. (Jr.). **Maximum sodium chloride intake and thirst in domesticated and wild Norway rats.** *Amer. J. Physiol.*, 1954, **176**, 213-222. [Dept. Psychiat., Johns Hopkins Sch. Med., Baltimore, Md.]

The 36 wild rats trapped shortly before the experiment began were compared with 36 Norway rats bred in the laboratory. The stock diet contained 5 per cent. salt butter and 1 per cent. NaCl; in the low-salt diet saltless butter was used and NaCl was omitted. Twelve groups of 3 rats of each strain received the low-salt diet alone or with from 2 to 70 per cent. of added salt until they died or until they were killed after from 72 to 92 days.

All the rats receiving 25 per cent. or less NaCl were healthy after from 89 to 92 days except one domesticated and 2 wild rats. With 35 per cent. NaCl 1 wild and 2 domesticated rats died and the other 3 were moribund when killed after 42 days. All the rats receiving 50 or 70 per cent. NaCl died; one domesticated rat survived 17 days on 70 per cent. NaCl. The rats learned to eat as much of the high-salt as they had previously eaten of the low-salt diet, except at the 2 highest salt concentrations. At 35 per cent. NaCl the salt intake was 23 g. per kg. bodyweight daily. Water intake increased abruptly and was then kept almost constant; the highest consumption was in rats on 25 per cent. NaCl. Both before and during the experiment the wild rats drank more than the domesticated rats, and the increases in water intake, except at 25 per cent. NaCl, were greater both absolutely and relatively to their pre-experimental intakes. The domesticated rats needed about 60 g. water per g. NaCl to maintain health. In rats without access to water a single dose of 3 or 4 g. NaCl per kg. bodyweight was lethal. At very high salt concentrations the rats were unable to satisfy their needs for energy and for water, though a few rats drank water equivalent to their bodyweight.—D. Duncan.

TOUSSAINT, C., WOLTER, R. and SIBILLE, P. Hypertension et lésions artérielles provoquées chez le rat par l'ingestion de quantités excessives de chlorure de sodium. [**Hypertension and arterial lesions in the rat after ingestion of large amounts of sodium chloride.**] *Rev. belg. Pathol. Méd. exp.*, 1953, **23**, 83-101. [Lab. Anat. Pathol., Univ. Brussels.] English summary.

Six groups of rats were selected according to weight and sex, and all received to appetite a diet with the percentage composition sugar 43, casein 30, arachis oil 15, salt mixture without NaCl 5, brewer's yeast 4, vitamin mixture 3. Controls received 1 per cent., experimental rats 2, 2.5 or 3 per cent., NaCl in the drinking water, and certain

of them received extra salt in the food when the drinking fluid failed to produce polydipsia.

With 2 or 2.5 per cent. NaCl, polydipsia occurred after about a week and reached as much as 100 ml. per 100 g. bodyweight in 24 hr. With the extra addition of 5 per cent. NaCl to the food, polydipsia and polyuria were even greater, but usually decreased within 24 hr. after withdrawal of the supplement. Rats receiving 2 per cent. saline did not show increased blood pressure, but with the higher intakes transient hypertension occurred in some animals, lasting 4 to 7 days. There was some relation between hypertension and plasma Na concentration; in some animals there was an increase in plasma N.P.N., but it did not appear to be related to plasma Na or to blood pressure.

In 16 of 27 rats examined there were arterial lesions of the heart and, in some of these, also of the pancreas and kidneys. The lesions are described and illustrated. The adrenal cortex showed atrophy in the glomerular zone in all the rats exposed to NaCl, and the hypothalamo-hypophyseal system showed enlarged cells and evidence of hypersecretion.—D. Duncan.

SPENCER, A. G. and LLOYD-THOMAS, H. G. L. **A critical analysis of cation-exchange therapy.** *Brit. Med. J.*, 1954, **i**, 597-603. [Med. Unit, University Coll. Hosp. Med. Sch., London, W.C.1.]

Thirty patients with cardiac and 9 with renal oedema were treated in bed on a low-salt diet with restricted fluid. After a control period cation exchange resins were given. The dose was generally 20 g. thrice daily after meals and treatment lasted from 2 to 8 weeks.

Treatment resulted in rapid loss of weight with water diuresis, and results were classified on the degree of weight loss. They were excellent in 13, considerable improvement was obtained in 8, and there was no definite improvement in 11; 7 had insufficient oedema to allow of this method of assessment. Treatment was most effective in patients with type II nephritis or chronic rheumatic heart disease without cardiac cirrhosis. Results were poor in patients with chronic congestive heart failure, renal failure or plasma Na below 130 m. equiv. per litre. Three patients died during treatment. Minor gastro-intestinal discomfort occurred in 67 per cent.

Na balance studies were made on 12 patients; in 8 there was a mean negative Na balance of 48 m. equiv. daily and in the grossly oedematous the total Na loss was great. The faecal Na loss varied greatly and might decline during prolonged treatment; loss of water and salt through the urine during the resin treatment was important. No sign of salt depletion was seen. Weakness associated with low plasma K was seen in 7 patients. There was little change in plasma Na, and blood urea rose only in patients with pre-existing renal failure. Signs of K depletion developed in 19 patients, and in 26 of 83 samples analysed the plasma concentration was below 4 m. equiv. per litre; the depletion arose from increased faecal K excretion. There was no evidence of Ca depletion, but there was a small loss of Mg.

The effectiveness of the treatment varied with intestinal motility; loose stools increased the Na loss, constipation decreased it. The resins were most effective when body Na was increased, unless plasma Na was low. Faecal Na loss was less when K intake was raised.—L. Wills.

3398

SPENCER, A. G., ROSS, E. J. and LLOYD-THOMAS, H. G. L. **Cation exchange in the gastrointestinal tract.** *Brit. Med. J.*, 1954, i, 603-606. [Med. Unit, University Coll. Hosp. Med. Sch., London, W.C.1.]

All the subjects had been treated with low-salt diet and cation exchange resins (see preceding Abst.). Analysis of the resin recovered from different parts of the intestinal tract showed that in the small intestine the resin had taken up large amounts of Na, 1.4 m. equiv. per g., compared with 0.5 m. equiv. K per g., but in the colon the Na and K uptakes became 0.9 and 0.8, and in the rectum 0.4 and 1.1 m. equiv. per g., respectively.

In 3 patients on a low-salt diet but without exchange resins the colon was washed out and 2 hr. later 5 g. cation exchange resin in the Na phase was introduced. The resin always lost Na and gained appreciable amounts of K and less Ca and Mg. With labelled isotopes to measure the net rate of exchange results of the same order were obtained.

In 7 constipated patients the stools were examined before and for 48 hr. after administration of an aperient which kept the faeces fluid. The mean faecal excretion of Na during this period increased from 21 to 69 m. equiv. and that of K from 69 to 103 m. equiv. daily; the Na bound to the resin increased from 0.32 to 0.68 m. equiv. per g. and the Na : K ratio rose from 0.26 to 0.73.

The net exchange of bound Na for K and other ions results from changes in the concentration and relative proportions of these ions in the fluids of the large bowel.—L. Wills.

GERSHON-COHEN, J. and McCLENDON, J. F. **Fluorine in tea and caries in rats.** *Nature*, 1954, 173, 304-305. [Dept. Radiol., Albert Einstein Med. Centre, Philadelphia, Pa.]

A caries-producing diet of cracked yellow maize 800, alfalfa meal 30, linseed meal 60, sucrose 250, maize oil 80, active dried yeast 50 and salt 10 g. was used, to which 1 g. fresh liver was added once weekly. The diet was given to 30 rats with strong infusions of tea which contained 20 p.p.m. F., and as a control group 30 littermates had water with 0.02 p.p.m. F. The experiment began when the rats were 23 days old and continued for 16 weeks, by which time only 11 pairs survived. No difference between the groups appeared in the extent of their failure to gain weight, of decalcification of their skeletons or of caries production.

In the absence of the expected effect on skeletal calcification it is thought that more attention should be paid to dietary Ca and P, especially in view of the differences in amounts of F which have been reported as necessary to prevent caries in rats (McClure and Mitchell, *J. Biol. Chem.*, 1931, 90, 297, and Gershon-Cohen and McCleendon, *Amer. J. Roentgenol.*, in press).—D. Harvey.

3401

RADIKE, A. E. and MUHLER, J. C. **The incidence of dental caries in hamsters receiving two different water-soluble fluorides at low concentrations.** *J. Dent. Res.*, 1953, 32, 807-810. [Dept. Chem., Indiana Univ., Bloomington.]

Groups of 30-day-old hamsters were fed for 90 days on a caries-producing diet, with drinking water containing 10 µg. fluoride per ml. as stannous fluoride or sodium fluoride, or distilled water; they were then killed, severity of caries was judged by microscopic examination of the molars and F, Ca and P were estimated in the femurs.

Stannous fluoride was much more effective than sodium fluoride in reducing both incidence and

N.A. and R., July 1954

severity of caries. Neither supplement impaired bone calcification. Less F was stored in the bones with stannous fluoride than with sodium fluoride. These results agree with those for the rat (Absts. 5468, Vol. 20; 3936, Vol. 21; Muhler *et al.*, *J. Amer. Dent. Assoc.*, 1953, **46**, 290).—W. M. Deans.

3402

MUHLER, J. C., NEBERGALL, W. H. and DAY, H. G. **Studies on stannous fluoride and other fluorides in relation to the solubility of enamel in acid and the prevention of experimental dental caries.** *J. Dent. Res.*, 1954, **33**, 33–49. [Dept. Chem., Univ. Indiana, Bloomington.]

In continuance of earlier work (Absts. 5468, Vol. 20 and 3936, Vol. 21) rats were given a caries-producing diet containing 3.3 p.p.m. F and a number of compounds were added to their drinking water to supply about 10 p.p.m. F. Teeth were examined for caries and for solubility of enamel in acid solutions. Mean values are tabulated for gains in bodyweight, number of carious lesions, their extent and distribution in different molars and the reduction in decay produced by each compound in comparison with distilled water.

In the first experiment only SnF_2 reduced caries significantly. A smaller reduction, greater in females than in males, occurred with HF and there was none with ammonium fluoroborate or NaF. In the second experiment NaF, SnF_2 and sodium hexafluorostannate were used, but only the two Sn compounds reduced the incidence. Increasing the pH of SnF_2 solution decreased its effectiveness in reducing caries. Stannous fluoroborate caused a good degree of reduction, PbF_2 did so to a less extent and Cu and Na fluoroborates were much less effective.

The F content of the right femur served as a measure of the amount of F stored by the skeleton. According to this criterion the amount retained from a particular compound was not useful as a measure of the degree of reduction of caries which the compound would produce. With two samples of SnF_2 which reduced caries to the same extent the amounts of F retained by the skeleton were not equal.

The effect of fluorides on the solubility of enamel in organic acids seemed to run parallel to their effect in reducing the incidence of caries.

MORIMOTO, H. and TAKAHASHI, S. [On the accumulation and distribution of iodine in the body of laying hens.] *Bull. Nat. Inst. Agric. Sci., Chiba, Japan* [G], 1953, No. 7, 175–180. In Japanese: English summary.

Small groups of laying hens were fed on a basal ration containing 0.4 mg. I per 100 g. or the same

ration with 50 mg. I as seaweed or 25 mg. I as thyroprotein. In 12 days the mean amount of I retained in the body was 81 per cent. of intake in the controls, 51 per cent. in those receiving seaweed and 65 per cent. in those receiving thyroprotein. The I concentration was highest in the thyroid, next in muscle and low in kidney, ovaries, liver and small intestine, but the total I accumulation was greatest in muscle, owing to the greater weight of the tissue. (From summary.)

IRON AND COPPER

3408

BADENOCH, J. and CALLENDER, S. T. **Iron metabolism in steatorrhoea. The use of radio-active iron in studies of absorption and utilization.** *Blood, J. Hematol.*, 1954, **9**, 123-133. [Nuffield Dept. Clin. Med., Radcliffe Infirmary, Oxford.]

In 16 subjects with steatorrhoea absorption of radio-active Fe given by mouth was poor compared with absorption in 15 controls without steatorrhoea. Subsidiary tests with some of the subjects indicated that Fe was better absorbed by the fasting than the fed subject and absorption was not improved by addition of ascorbic acid to the test dose.

In a small group of subjects with steatorrhoea radio-active Fe given intravenously was rapidly and completely utilised.

It is suggested that poor absorption of Fe may not be the sole cause of anaemia in steatorrhoea. There may be excessive loss of Fe.—F. C. Aitken.

MESSERLI, H. **Untersuchungen über Eiweissmangel als Ursache der Hämochromatose. [Protein deficiency as a cause of haemochromatosis.]** *Internat. Ztschr. Vitaminforsch.*, 1954, **25**, 225-240. [Pathol. Inst., Univ. Berne.] English and French summaries.

When young rats were given protein-deficient diets providing 5 per cent. protein for 5 weeks and 3 per cent. for 13 weeks, with 2 per cent. Fe citrate, there was deposition of Fe in the tissues in the form of haemosiderosis, but without morphological signs of haemochromatosis. The localisation of Fe in the cells was much the same as in ordinary haemosiderosis. The experiments gave no support for the idea that haemochromatosis is caused by protein deficiency.—M. B. Richards.

HAMPTON, J. K. (Jr.) **Uptake of radioiron in tissue storage compounds in normal and hemolytic mice and its utilization for erythropoiesis.** *Amer. J. Physiol.*, 1954, **176**, 20-24. [Dept. Physiol., Sch. Med., Tulane Univ., New Orleans, La.]

Nine normal mice each received an intravenous injection of 75 μg . ^{59}Fe as citrate 4 days before being killed. The distribution of ^{59}Fe in the tissues was studied. Liver homogenates were divided as described by Hampton and Kahn (Abst. 847, Vol. 24) into haemosiderin-rich (HRF) and ferritin-rich (FRF) fractions. The proportion of ^{59}Fe in the FRF was about 17 per cent., and little greater than that in the HRF.

Haemosiderosis was produced in 9 mice by intravenous injection of 4 mg. saccharated Fe oxide 7 days before the ^{59}Fe injection. The haemosiderosis did not affect ^{59}Fe uptake by the kidney, spleen or HRF, but the specific activity of the blood was only half that found in the controls. The total FRF was 7 times that in controls, and its ^{59}Fe content was 14.7 μg . compared with 8.8 μg . in controls. The entire injected dose was only one-fifth the size of the total FRF, so the capacity of the latter was not severely tested.

In 6 mice which had been bled 7 days after the ^{59}Fe injection and killed 11 days later the specific activity of the blood showed twice as much ^{59}Fe utilisation as in controls. The total Fe in the FRF was about half that in controls, but the HRF was unchanged. Both fractions showed considerable reduction of ^{59}Fe , indicating that both ferritin and haemosiderin Fe were available for metabolism. It is suggested that the Fe last received was first used for blood formation and that mixing of ^{59}Fe with previously stored Fe was incomplete.—D. Duncan.

CALHOUN, J. A., McLEAN, R., HUDSON, J. C. and AUB, J. C. **Comparative exchange of calcium, lead, and radioactive lead in dogs.** *Arch. Indust. Hyg.*, 1954, **9**, 9-22. [Med. Labs., Collis P. Huntington Mem. Hosp., Massachusetts Gen. Hosp., Boston.]

Lead is considered to behave in the bones like Ca.

Two dogs received inert Pb in 6 injections during 12 to 18 days, without ill effect. Ten others received Pb mixed with radium D, ^{210}Pb , in amounts from 0.2 to 2.3×10^{-1} mC. per kg. body-weight. Metabolic studies were continued for 3 or 4 months on the 2 former and 4 of the latter, and the effects of high and low Ca intakes and parathyroid extract were compared.

More Pb and ^{210}Pb was excreted in urine than in faeces. Roughly 67 per cent. of the ^{210}Pb excreted was in urine. ^{210}Pb was toxic, the toxicity being proportional to the amount of radio-activity; 5 of the dogs were found dead from 6 to 136 days after the injections and the other 5 were killed when their condition deteriorated, 142 to 246 days after the injections. In those which survived for several months 60 to 80 per cent. of the injected ^{210}Pb was excreted. Parathyroid extract and Ca intake did not affect ^{210}Pb excretion.

After some months those dogs on metabolism trials which had received ^{210}Pb showed increasing abnormalities of urine composition, excretion of albumin and sugar, epithelial casts and low sp. gr. One had terminal haematuria.

The pathology of the kidney differed from that in other radiation injury. Bone marrow injury was found in 2 dogs.—D. Duncan.

3415

McLEAN, R., CALHOUN, J. A. and AUB, J. C. **Migration of inorganic salts in bone as measured by radioactive lead and by alizarin.** *Arch. Indust. Hyg.*, 1954, **9**, 113-121. [Med. Labs., Collis P. Huntington Mem. Hosp., Massachusetts Gen. Hosp., Boston.]

Bone and tooth samples were obtained from the dogs described in the preceding paper. The amounts of ^{210}Pb in these tissues depended on the total amount of Pb given. Storage of ^{210}Pb was 5 to 16 times as great in the trabeculae as in the cortex, less in dentine than in cortex and not detectable in tooth enamel.

In cats fed on madder and killed immediately the dye was almost confined to the trabeculae, but when several months elapsed between madder feeding and death the trabeculae were pearly white and the cortex pink. This demonstrates the migration of Ca from the trabeculae to the cortex

and its relative stability in the cortex. The ^{210}Pb was less sensitive as an indicator, but also suggested transport from trabeculae to cortex.

JAFFE, W. G. Cobalto en la reproduccion de ratones y ratas. Ensayos con dietas altas y proteinas. [Cobalt in reproduction of mice and rats. Trials with high-protein diets.] *Arch. venezol. Nutricion*, 1952, **3**, 335-341. [Inst. Nac. Nutrición.] English and German summaries.

The effect of Co supplementation of a diet high in protein and low in vitamin B₁₂ was investigated in reproduction tests on rats and mice which had been bred for several generations on a vegetarian diet low in vitamin B₁₂. Pregnant females were given a diet containing 40 per cent. protein, half of them receiving a 0.005 per cent. solution of CoCl₂ as drinking water.

In the groups given Co there was an increase in the average weaning weight of the young from 36.4 to 44.2 g. and from 30.8 to 33.5 g. in 2 series of rat experiments, and from 9.0 to 10.4 g. in mice, but the increases were not statistically significant. There was also an increase, again not significant, in the number of surviving young per litter born.

The beneficial effects of Co supplementation on the high-protein diet were less than in previous experiments with diets of normal protein content, and possible reasons for the difference are discussed.—M. B. Richards.

KULWICH, R., HANSARD, S. L., COMAR, C. L. and DAVIS, G. K. **Copper, molybdenum and zinc interrelationships in rats and swine.** *Proc. Soc. Exp. Biol. Med.*, 1953, **84**, 487-491. [Atomic Energy Commission Agric. Res. Program, Univ. Tennessee, Oak Ridge.]

Weanling rats and 10-week-old pigs were given for 14 and 27 weeks, respectively, diets containing supplementary Mo, Cu or Zn. During the week before slaughter radio-active Cu was given by mouth.

In rats, liveweight increase was not affected by Cu, 200 p.p.m., or Zn, 1000 p.p.m., but was reduced by Mo, 1000 p.p.m. Very high concentrations of total and radio-active Cu were found in the tissues, particularly in the liver and kidneys, of rats which received Mo. This was not much altered by the addition of 200 p.p.m. Cu to the Mo diet.

In pigs accumulation of Cu in liver and kidney took place in animals which received Mo, but there was little retardation of growth and food utilisation was not impaired.—R. Hill.

FRIEDEL, W. Über Stickstoff- und Schwefelausscheidung im Urin bei Säuglingen mit akuten Ernährungsstörungen. [**Excretion of nitrogen and sulphur in the urine of infants with acute disturbances of nutrition.**] *Deutsch. Ztschr. Verdauungs- u. Stoffwechseler.*, 1953, **13**, 257-261. [Kinderklin., Univ. Leipzig.]

In infants without intestinal disturbance neutral S in the urine formed from 5.3 to 11.7 per cent. of the total S and the N : S ratio was between 12.6 and 16.3. These may be regarded as normal. In infants suffering from severe nutritional disturbances the percentage of neutral S in the urine ranged from 24.4 to 51.3, and the N : S ratio from 3.9 to 8.4. It is considered that the low N : S ratio may be a sign of regenerative metabolism after acute nutritional disturbance, the endeavour to make up N loss leading to increased retention of dietary N and so diminishing the N : S ratio in the urine.—M. B. Richards.

WÜST, H. Verhalten der Harnsulfate und der Gesamtstickstoffausscheidung nach Einnahme elementaren Schwefels beim Menschen. [**Behaviour of urinary sulphates and total nitrogen excretion in man after ingestion of elemental sulphur.**] *Ztschr. ges. exp. Med.*, 1954, **123**, 171-176. [Inst. Physiol., Med. Akad., Düsseldorf.]

The excretion of sulphates in the urine of healthy human subjects was studied after intake of preparations of the element S. The magnitude of the excretion depended on the size of the S particles ingested. It was greatest for "Sulfactol", a preparation of finely divided S, and amounted to 78 per cent. of the intake; a distinct increase in excretion was evident 2 to 4 hr. after ingestion, indicating rapid absorption of S from the intestine. With precipitated S, 36 per cent. was excreted as sulphate, the increase showing only after 4 to 6 hr. An unexpected result was the fall in urinary sulphates, after the initial increase, when medication was continued for several days. No significant change in urinary excretion of N was found during the experiment.—M. B. Richards.

METABOLISM OF WATER

of water in the rat during prolonged protein fast. *C.R. Soc. Biol.*, 1953, **147**, 1471-1475.

Rats were depleted of protein in 4 or 6 weeks, losing between 20 and 47 per cent. of their initial bodyweight. At the end each received an intramuscular injection of sodium thiocyanate, 95 mg. per kg. bodyweight, and was killed 1 hr. later. The difference between thiocyanate space and total water content represented the intracellular water.

After 4 weeks of depletion the average loss of total protein was 13 per cent. and that of total water 29 per cent. Extracellular water increased, and after 6 weeks was 60 to 80 per cent. above the initial value. Plasma albumin decreased considerably.—D. Duncan.

PRESTON, E. (III), HUNT, A. D. (Jr.), SCOTT, T. F. M. and SPUR, B. **Short-term feeding studies in infants and children with certain surface-active agents used in food technology: absence of evidence of toxic effects.** *J. Clin. Nutr.*, 1953, **1**, 539-550. [Child. Hosp., Philadelphia, Pa.] Spanish summary.

Two children were given 4 g. sorbitan monostearate (Span 60) daily for 37 and 32 days; 3 infants were given 1 g. polyoxyethylene (20) sorbitan monostearate (Tween 60) daily for 31, 34 and 13 days; 2 children were given 4 g. polyoxyethylene (8) stearate (Myrj 45) daily for 16 and 14 days. These children were classed as normal for the purposes of the study. They showed no obvious harmful effect and a follow-up of 4 of them 4 to 6 months later showed normal progress. There was no gross laboratory evidence of toxicity in blood counts, urine analyses, pancreatic enzymes, gastrointestinal X-ray studies or analyses of stools for fat and nitrogen.

One infant suffering from "mucoviscidosis" was given Tween 60 for 12 days. This infant died. F. C. Aitken.

LUCAS, J. and ORTEN, J. M. **Dietary protein and glycine as precursors of porphyrins in the rat.** *J. Nutrition*, 1954, **52**, 89-97. [Dept. Physiol. Chem., Coll. Med., Wayne Univ., Detroit, Mich.]

Groups of 6 or 12 rats weighing from 180 to 200 g. received a basal diet of percentage composition casein 20, maize oil 23, cod liver oil 2, sucrose with vitamins 10, dextrin 41 and salt mixture 4. One group received the basal diet only, one the basal diet for 4 weeks and a low-protein diet for 4, one the basal diet with 2 per cent. glycine for 4 weeks and without for 4, the fourth basal diet with sodium benzoate 3 per cent. for 4 weeks and 10 per cent. for 4, and the fifth the basal diet supplemented

with 3 per cent. sodium benzoate and 2 per cent. glycine for 4 weeks and then with 10 per cent. sodium benzoate and 5 per cent. glycine. Total and individual porphyrins were estimated in pooled samples of faeces.

Glycine slightly increased porphyrin formation and sodium benzoate or protein restriction diminished it. Glycine reduced the inhibitory effect of sodium benzoate. Protoporphyrin made up about half the total faecal porphyrin; coproporphyrin and uroporphyrin occurred only in traces, so the "total porphyrin" procedure measured also some unidentified non-porphyrin pigments. Rats on basal diet constantly excreted about 35 µg. protoporphyrin per g. protein ingested and this was decreased by benzoate; but on low-protein diet the amount rose to 153 µg. per g. protein. A high priority for porphyrin formation appears to exist when either protein or glycine is restricted.—D. Duncan.

MITCHELL, R. G. and CODE, C. F. **Effect of diet on urinary excretion of histamine.** *J. Appl. Physiol.*, 1954, **6**, 387-392. [Sect. Physiol., Mayo Found., Rochester, Minn.]

After 3 days on mixed diet, 5 healthy adults fasted for 3 days, then had bread and milk diet for 2 days, followed by a meat diet for 3 days. In each subject the mean daily excretion of both free and conjugated histamine was less during fasting than on mixed diet. Bread and milk did not significantly increase excretion above the fasting levels, but the meat diet did. In general the output of conjugated histamine showed more pronounced changes than that of free histamine.

When histamine was given to fasting subjects by mouth, no change occurred in the urinary output of free histamine, but large amounts of conjugated histamine appeared from the third hour onwards. No change in the output of free histamine occurred after a meal of bread, milk and butter, but a sharp increase occurred if the meal and histamine were given together.

SCHLÜSSEL, H. **Beitrag zur Verwertung mehrwertiger Alkohole in der Ernährung. [Utilization of polyhydric alcohols in the diet.]** *Arch.*

exp. Pathol. Pharmacol., 1954, **221**, 67-75.
[Med. Klin., Univ. Cologne.]

In preliminary experiments female albino rats weighing about 70 g. were fed individually on a basic diet of oat flakes 60, glucose 20.3, gelatine 10, butterfat 5 and minerals 3.7 per cent. or the same with 5, 10, 20, 30 or 40 per cent. of the energy supplied by one of 7 polyhydric alcohols at the expense of glucose or glucose and oat flakes. 1:6-Hexanediol, 2:5-hexanediol, 1:4-butanediol and 1:2:4-butanetriol were found to be toxic.

Further trials with 8 rats on each diet were made with 1:3-butanediol, which is an intermediate in the manufacture of Buna rubber,

mesoerythritol and 1:2-butanediol, and with a diet in which 1:3-butanediol supplied 10, mesoerythritol 5, 1:2-butanediol 5 and *Torula utilis* 20 per cent. of the energy.

The least toxic was 1:3-butanediol, no toxic sign being found below the 30 per cent. level; mesoerythritol was tolerated at the 10 per cent. level and 1:2-butanediol at the 5 per cent. All these in non-toxic amounts, and also the mixture with yeast, improved total energy intake, weight gain and feeding efficiency compared with the basic diet. The suggestion is made that small quantities of polyhydric alcohols, preferably 1:3-butanediol, might be tested on fattening livestock.

PENNINGTON, R. J. The metabolism of short-chain fatty acids in the sheep. 2. Further studies with rumen epithelium. *Biochem. J.*, 1954, **56**, 410-416. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Rumen epithelial tissue was incubated as described in Abst. 2562, Vol. 22. The rate of metabolism of acetic, butyric and propionic acids was studied under different concentrations of CO₂ in the gas phase and in the presence of malonate, fumarate and ammonium ions.

The rate of metabolism of propionic acid increased with increasing concentrations of CO₂ up to 20 per cent. of the gas phase, the other 80 per cent. being O₂; no such effect was noted on the rate of disappearance of acetate and butyrate. In the presence of malonate utilisation of each fatty acid was inhibited; ketone body production from butyrate was depressed, but little effect was observed on the proportions of ketone bodies formed. Succinate was produced when propionate was metabolised in the presence of malonate. Butyrate metabolism was not affected by the

presence of ammonium ions, though propionate, and possibly acetate, metabolism was inhibited. In the absence of CO₂ propionate depressed the oxygen uptake of the tissue: respiration was, however, stimulated by propionate in the presence of CO₂.

CASTEN, G. G. and MARSH, J. B. Metabolic studies on cardiac tissue obtained by needle biopsy in the intact unanesthetized dog. *Circulation Res.*, 1953, **1**, 226-229. [Dept. Cardiorespiratory Dis., Army Med. Serv. Grad. Sch., Walter Reed Army Med. Centre, Washington, D.C.]

Dogs were subjected to a preliminary operation in which the apex of the heart was anchored to the chest wall. After 10 days biopsy specimens could be obtained from the myocardium. A series of samples could be taken from the same animal, one-third of the 65 dogs having had 8 or 10 biopsies each involving from 3 to 5 cardiac punctures; a limit was imposed by the development of fibrosis.

Glycogen content of the biopsy specimens was not affected by anaesthesia. Administration of the digitalis preparation lanatoside-C significantly increased the glycogen content. Formation of glycogen from glucose *in vitro* could not be demonstrated. The average oxygen uptake was 30 μ M per g. wet tissue per hr., resembling that of surviving heart slices *in vitro*. The mean N content was 32.6 mg. per g. wet weight.

MILLER, L. L. and BALE, W. F. **Synthesis of all plasma fractions except gamma globulins by the liver. The use of zone electrophoresis and lysine- ϵ - C^{14} to define the plasma proteins synthesized by the isolated perfused liver.**

MILLER, L. L., BLY, C. G. and BALE, W. F. **Plasma and tissue proteins produced by non-hepatic rat organs as studied with lysine- ϵ - C^{14} . Gamma globulins the chief plasma protein fraction produced by non-hepatic tissues.** *J. Exp. Med.*, 1954, **99**, 125-132; 133-153. [Dept. Radiation Biol., Sch. Med. Dent., Univ. Rochester, N.Y.]

Plasma specimens were obtained from rat livers perfused with plasma containing lysine- ϵ - ^{14}C under conditions reported earlier (*J. Exp. Med.*, 1951, **94**, 131) and also from rats which had received intraperitoneal injections of DL-lysine- ϵ - ^{14}C 6 hr. before blood was drawn. Plasma proteins were fractionated by the method of Kunkel and Slater (*Proc. Soc. Exp. Biol. Med.*, 1952, **80**, 42). The isolated perfused liver incorporated ^{14}C into the plasma albumin and α - and β -globulins, but not into γ -globulin. The γ -globulin from the plasma of intact rats contained ^{14}C . There was evidence that the α -globulins turn over more rapidly than other major plasma fractions. In all samples they had more specific activity than any other fraction.

The non-hepatic tissues in a "carcase" (caudal half of the rat) perfused with plasma as above for 6 hr. showed good clearance of lysine- ϵ - ^{14}C and glucose from the perfusate and formation of tissue and plasma proteins. ^{14}C -labelled plasma proteins obtained from an eviscerated surviving rat 6 hr. after intravenous injection of lysine- ϵ - ^{14}C showed most of its ^{14}C activity in the γ -globulins, with slight activity in the α - and β -globulins but none in the albumin fraction.—W. Godden.

3439

KRUHÖFFER, P. and MUNTZ, J. A. **Carbohydrate metabolism of the isolated, perfused cat liver as studied by labelled glucose and fructose.** *Acta physiol. scand.*, 1954, **30**, 258-274. [Inst. Med. Physiol., Univ. Copenhagen.]

Isolated cat livers perfused with blood readily utilised DL-alanine or fructose. Glucose was released to the blood; blood sugar increased when alanine was given, and glycogen formation was

slight or absent. With fructose glycogen was deposited and blood sugar rose. When radio-active glucose was added to the blood between 7 and 10 per cent. was deposited in glycogen, and this was increased by addition of inactive fructose. When radio-active and inactive fructose were given much more of the radio-activity appeared in glycogen and in CO_2 .

Thus although there was no net uptake of glucose, glucose was metabolised. Much of it was incorporated into glycogen as an intact unit, thought to be evidence of direct phosphorylation. The actual rate of phosphorylation may have been as high as 2.6 mg. per min. per 100 g. tissue. The rate of fructose phosphorylation was at least 30 mg. per min. per 100 g.—D. Duncan.

3440

FRUNDER, H. and FRIEDEL, W. **Über die Sauerstoffaufnahme von Schnitten experimentell verfetteter Lebern. [The oxygen uptake of slices of experimental fatty livers.]** *Hoppe-Seyler's Ztschr.*, 1953, **295**, 77-83. [Physiol. Chem. Inst., Univ. Leipzig.]

HAUGAARD, E. S. and HAUGAARD, N. **The effect of hyperglycemic-glycogenolytic factor on fat metabolism of liver.** *J. Biol. Chem.*, 1954, **206**, 641-645. [John Herr Musser Dept. Res. Med., Univ. Pennsylvania, Philadelphia.]

Rats were fed on a stock diet to which bread was added on the day before they were killed. Liver slices were prepared and incubated for 3 hr. at 38° C. in Krebs Ringer bicarbonate buffer containing ^{14}C -labelled glucose or fructose, with or without the addition of hyperglycaemic-glycogenolytic factor (HGF: see Sutherland and de Duve, *J. Biol. Chem.*, 1948, **175**, 663-674). At the end of the incubation fatty acids were isolated and their ^{14}C -content was estimated. Fatty acid formation from both glucose and fructose was reduced by about 30 per cent. in the presence of HGF.

In further experiments liver slices prepared in the same way were incubated for 90 min. at 38° C. in Krebs Ringer bicarbonate buffer with or without Na acetate and in the presence or absence of HGF. Total ketone production was measured at the end of the incubation period. Ketone body production was increased in the presence of HGF whether or not acetate was present.—G. A. Garton.

3442

FRANTZ, I. D. (Jr.) and BUCHER, N. L. R. (with SCHNEIDER, H. S., MCGOVERN, N. H. and KINGSTON, R.) **The incorporation of the carboxyl carbon from acetate into cholesterol by rat liver homogenates.** *J. Biol. Chem.*,

1954, **206**, 471-481. [Cardiovascular Res. Lab., Dept. Med., Harvard Med. Sch., Boston, Mass.]

Cell-free homogenates from the livers of female rats were incubated for 2 hr. at 37° C. with acetate labelled with ^{14}C in the carboxyl group. Cholesterol was then isolated as the digitonide and rigorously purified through the dibromide and acetylation. The radio-activity was measured at all stages of the purification.

It was concluded that the radio-active material precipitated by digitonin was mainly cholesterol digitonide.—G. A. Garton.

3443

HOTTA, S., HILL, R. and CHAIKOFF, I. L. **Mechanism of increased hepatic cholesterogenesis in diabetes: its relation to carbohydrate utilization.** *J. Biol. Chem.*, 1954, **206**, 835-844. [Dept. Physiol., Sch. Med., Univ. California, Berkeley.]

Normal and alloxan-diabetic rats were fed on high-glucose or high-fructose diets before being killed. Liver slices were incubated with ^{14}C -labelled acetate as described by Chernick *et al.* (Title 2382, Vol. 20). Cholesterol was isolated as digitonide from the incubation mixture and assayed for ^{14}C activity.

The capacity of liver slices of diabetic rats fed on glucose to incorporate ^{14}C -acetate into cholesterol was more than double that of slices from normal rats fed on either the high-glucose or the high-fructose diet. Fructose, on the other hand, appeared to be used for cholesterol synthesis at the normal rate in the diabetic liver slices. Liver slices from diabetic rats fed on the high-fructose diet showed a normal rate of incorporation of labelled acetate into cholesterol.—G. A. Garton.

3444

POPJÁK, G. **Biosynthesis of squalene and cholesterol in vitro from acetate- 1-C^{14} .** *Arch. Biochem. Biophys.*, 1954, **48**, 102-106. [Nat. Inst. Med. Res., Mill Hill, London.]

Liver slices from young rats and ovarian membranes (*granulosa* and *theca interna*) from laying hens incubated with acetate- $1\text{-}^{14}\text{C}$ synthesised both squalene and cholesterol.

According to the evidence presented, squalene is neither the immediate precursor of cholesterol nor an intermediate in its biosynthesis, though it may provide isoprenoid units for sterol anabolism.

KITTINGER, G. W. and REITHEL, F. J. **Lactose synthesis in mammary gland preparations.** *J. Biol. Chem.*, 1953, **205**, 527-533. [Dept. Chem., Univ. Oregon, Eugene.]

Homogenates were prepared of mammary tissue from lactating guineapigs 5 days *post partum*. For some of the tests a soluble protein preparation was made by extracting the minced glands with 0.2 M potassium citrate at pH 7.3. After centrifuging, the protein was precipitated with ethanol, suspended in 0.02 M potassium citrate and lyophilised. The preparations were usually completely soluble in water.

Lactose was synthesised from glucose- ^{14}C by homogenates only in the presence of added adenosinetriphosphate. Fermentation experiments with *Saccharomyces bayanus* and *S. carlsbergensis* suggested that the glucose and galactose moieties of the lactose so formed were equally labelled with ^{14}C . Lactose was synthesised by the homogenates from labelled starch in the absence of ATP. Lactose formation was not accelerated by addition of hexokinase or coenzyme I. Glycogen was formed from glucose or glucose-1-phosphate in homogenates of lactating, but not of regressive, glands.

The protein preparation catalysed the formation of lactose from labelled starch, but not from glucose-1-phosphate. Hexokinase activity was present, as both glucose and fructose disappeared when incubated with the preparation in the presence of ATP. Glucose-1-phosphate was converted to glycogen in the presence of added glycogen, but not in its absence. Neither starch nor glucose-1-phosphate was converted to pyruvic or lactic acid.

D. Duncan.

BALMAIN, J. H., FOLLEY, S. J. and GLASCOCK, R. F. **Relative utilization of glucose and acetate carbon for lipogenesis by mammary-gland slices, studied with tritium, ^{13}C and ^{14}C .** *Biochem. J.*, 1954, **56**, 234-239. [Nat. Inst. Res. Dairying, Univ. Reading.]

Sliced mammary tissue from lactating rats and ewes was incubated in a medium containing ^{14}C -labelled glucose and carboxy- ^{13}C -Me- ^3H -labelled acetate. At the end of 3 hr., mixed fatty acids were isolated as Ca salts and the 3 isotopes present were estimated.

Rat gland incorporated about 8 times as much glucose carbon and about one-sixth as much acetate carbon into fatty acids as did slices from the sheep gland. Rat mammary gland tissue used acetate carbon or glucose carbon at about the same rate for fatty acid synthesis; sheep udder tissue, in a given time, used about 30 times as much carbon from acetate as from glucose. Compared with the utilisation of glucose alone, rat gland utilised less glucose for fatty acid synthesis when acetate was

N.A. and R., July 1954

also present in the medium; acetate had no effect on the small utilisation of glucose by sheep gland. When added to the incubation medium, insulin promoted the utilisation of carbon atoms from glucose and acetate for fatty acid synthesis to about the same extent in rat gland; glycerol enhanced the conversion of acetate carbon to fatty acid to a greater extent than it promoted the utilisation of glucose carbon. Both carbon atoms of acetate were incorporated into fatty acid chains to about the same extent in both rat and sheep gland. During chain elongation about two-thirds of the hydrogen of acetate was lost or exchanged.

POPJÁK, G. and TIETZ, A. **Biosynthesis of fatty acids by slices and cell-free suspensions of mammary gland.** *Biochem. J.*, 1954, **56**, 46-54. [Nat. Inst. Med. Res., Mill Hill, London.]

Tissue slices and cell-free suspensions from the mammary glands of lactating rats and a lactating sheep were incubated for 3 hr. at 37.5°C. with [carboxy-¹⁴C] acetate in the presence of air or oxygen. Other substrates, glucose, adenosine-triphosphate (ATP), pyruvate, oxaloacetate, citrate, α -oxoglutarate, succinate, malate and glutamate were added to the incubation flasks as required. Oxygen consumption was measured and CO₂ was collected for estimation of radio-activity. At the end of incubation fatty acids were extracted from the slices or suspensions and fractionated chromatographically and their radio-activity was estimated.

In tissue slices glucose, pyruvate and other components of the citric acid cycle stimulated formation of fatty acid from acetate; the stimulation was especially effective in sheep udder tissue. Cell-free preparations from both rat and sheep tissue formed fatty acids from acetate. With rat mammary gland suspensions, the best results were obtained in the presence of oxaloacetate and ATP and under air. Fatty acid was formed by suspensions of sheep's udder in the presence of acetate alone; oxaloacetate had a stimulating effect, but ATP inhibited synthesis. Rat mammary gland suspensions did not oxidise acetate but similar preparations from sheep's udder did. All the saturated *n*-fatty acids containing an even number of C atoms from hexanoic to stearic and also oleic acid were identified in the rat mammary gland suspensions.—G. A. Garton.

PEETERS, G., COUSSENS, R. and SIERENS, G. **The metabolism of propionic, butyric and β -hydroxybutyric acids in the perfused isolated cow's mammary gland.** *Arch. internat. Pharmacodyn.*, 1953, **95**, 153-171. [Dept. Pharmacol., Vet. Sch., Univ. Ghent.] French summary.

Udders were removed from normal lactating cows and bisected along the median septum. Each half was perfused for from 90 to 120 min. with 9 litres of heparinised and oxygenated blood at 38°C. By a constant drip device, 150 ml. solution containing one of the following was added to the oxygenated blood: Na propionate 15 g.; Na propionate 10 g. plus glucose 10 g.; glucose 15 g.; Na acetate 12 or 15 g.; Na acetate 15 g. plus Na propionate 10 g.; Na butyrate 12 g.; Na butyrate 8 g. plus glucose 10 g.; Na acetate 10 g. plus Na butyrate 8 g. plus glucose 10 g.; Na β -hydroxybutyrate 10 g. plus glucose 10 g.; Na β -hydroxybutyrate 10 g. plus Na acetate 12 g.; Na β -hydroxybutyrate 10 g. In several experiments no addition was made to one half of the udder, which served as control. Blood samples were taken periodically for estimation of glucose, acetoacetic acid, acetone, isopropanol, total ketone bodies and pyruvic acid. R.Q. values were calculated from the oxygen and CO₂ content of the arterial and venous blood supplies. Insulin was sometimes added to the perfusion fluid.

Oxygen uptake was considerably increased when Na propionate, butyrate or β -hydroxybutyrate was added to the arterial blood; and R.Q. was: Na propionate 0.73, Na butyrate 0.71, Na β -hydroxybutyrate plus glucose 0.79. In the presence of Na butyrate the isolated gland did not respond to insulin. In the presence of butyrate traces of acetoacetic acid were formed. No ketone bodies were formed from acetate. Considerable amounts of acetone, acetoacetic acid and isopropanol were produced from β -hydroxybutyrate. In the presence of butyrate or β -hydroxybutyrate, the addition of acetate stimulated respiration and produced a higher R.Q. Acetic acid was metabolised more rapidly than propionate, butyrate or β -hydroxybutyrate.

G. A. Garton.

SCHMIDT, H. and STAUDINGER, HJ. **Stoffwechsel der Nebennierenrinde und Biosynthese der Corticosteroide. 4. Der Einfluss von C₄-Dicarbonsäuren auf die Biosynthese der Corticosteroide. [Metabolism of the adrenal and biosynthesis of corticosteroids. 4. Effect of C₄-dicarboxylic acids on biosynthesis of corticosteroids.]** *Biochem. Ztschr.*, 1954, **325**, 148-155. [Zentrallab., Städt. Krankenanst., Mannheim.]

Incubation experiments on homogenates prepared

from the adrenal glands of pigs showed that succinic, fumaric, malic and oxaloacetic acids increased formation of corticosteroids. At the optimum pH, between 7.2 and 7.4, oxaloacetate increased the yield of corticosteroids, as estimated chromatographically, by 80 to 100 per cent., succinate and fumarate by 70 to 80 and malate by 40 to 60 per cent. Na citrate at pH 7.4 had no activating effect. It is presumed that the C₄-dicarboxylic acids act as hydrogen carriers to the system.—M. B. Richards.

DINNING, J. S., NEATROUR, R. and DAY, P. L. **Effect of diet on rat liver betaine transmethylase.** *Proc. Soc. Exp. Biol. Med.*, 1953, **84**, 499-501. [Dept. Biochem., Univ. Arkansas Sch. Med., Little Rock.]

Betaine transmethylase activity of liver was estimated by the method described in Abst. 1806, Vol. 21. The livers of rats on a basal diet showed no appreciable activity. When the diet was supplemented with amino-acids or proteins only the combination containing cystine, threonine, phenylalanine and tryptophan was effective, and of these amino-acids, given singly, only tryptophan caused appreciable activity.

There was no correlation between the growth of rats and the activity of their livers, which suggests that the amino-acid patterns required for these functions differ considerably.—D. Harvey.

MINDER, W. and GORDONOFF, T. **Modellversuche über den Calciueinbau im Knochen. [Model experiments on calcium incorporation into bone.]** *Schweiz. med. Wochenschr.*, 1953, **83**, 825-828. [Radium Inst., Berne.]

Preparations from the same sample were made of fresh bone powder, bone powder heated at 800°C., and powdered apatite. Powders of different particle size were analysed. Radio-active ⁴⁵CaCl₂ in solution was added to them in suspension, and they were left to stand; samples were withdrawn from time to time and thoroughly washed and their content of ⁴⁵Ca was estimated. The greatest uptake was within the first hour, but ⁴⁵Ca content went on increasing slowly for more than 10 hr. The amount taken up by apatite was small. Heated bone took up 4 times as much as apatite, and fresh bone 2.85 times as much as heated bone.

The size of the particles and the concentration of ⁴⁵CaCl₂ did not affect the rate of uptake.

From the changes in the rate of uptake, it was concluded that the effect was probably not purely superficial, but that ⁴⁵Ca penetrated into the structure of the crystals. In support of the conclusions it was found that by washing with HCl about half the ⁴⁵Ca could be removed from the powders. From ion exchange experiments of the radio-active powders against water or non-radio-active CaCl₂ solutions of different strengths, the same conclusion was drawn; with the highest concentration of CaCl₂ only $\frac{3}{8}$ of the ⁴⁵Ca was withdrawn.—E. M. Hume.

FISCHER, R. B., MUHLER, J. C. and WUST, C. J. **Effects of several fluoride reagents on the surface structure of powdered dental enamel.** *J. Dent. Res.*, 1954, **33**, 50-54. [Dept. Chem., Univ. Indiana, Bloomington.]

Powdered dental enamel was treated with a number of reagents and changes in enamel structure as demonstrated by electron and X-ray diffraction patterns were studied. KF caused transformation of apatite to calcium fluoride structure, the rate of change increasing as pH was reduced; sodium silicofluoride caused the same change but at a slower rate. Sodium monofluorophosphate did not affect the structure. With SnF₂ even after very brief treatment the apatite structure was changed to an amorphous one, but it was not possible to decide whether the surface itself had been changed or whether some amorphous substance had been deposited on it.

D. Harvey.

WILSON, J. W. **Nutritional deficiency produced in the mouse by feeding bentonite. Hepatomas in mice on a diet containing bentonite.** *J. Nat. Cancer Inst.*, 1953, **14**, 57–63; 65–75. [Arnold Biol. Lab., Brown Univ., Providence, R.I.]

When bentonite, a base-exchange silicate, was given to mice as 50 per cent. of a synthetic diet they developed fatty livers and other signs of choline deficiency. Replacement of the bentonite by pure cellulose (Ruffex) or by BaSO₄ did not produce the same effects. Choline or protein added to the 50 per cent. bentonite diet improved growth and prevented fatty degeneration. It is concluded that choline, amongst other things, was removed by the bentonite.

In other experiments 12 mice were maintained

on the 50 per cent. bentonite diet and, after more than 200 days, hepatomas were found in all but one. Earlier work (Title 2417, Vol. 21) had shown that such tumours occurred in mice on diets low in protein and deficient in choline, and it is suggested that conditions favouring their appearance were produced by bentonite.—D. Harvey.

DOUGLAS, J. W. B. and MOGFORD, C. **The results of a national inquiry into the growth of premature children from birth to 4 years.** *Arch. Dis. Childhood*, 1953, **28**, 436–445. [Inst. Child Health, Univ. London.]

This is a follow-up of the premature children (those weighing 5½ lb. or less at birth), multiple and illegitimate births excluded, of the national survey of March 1946 ("Maternity in Great Britain", Royal College of Obstetricians and Gynaecologists and Population Investigation Committee, 1948). They were paired for sex, place in family, locality, social class and age of mother with full-term infants born during the survey week. Of the original 676 pairs, 464 were still available in 1950; height and weight measurements at ages 2 years and 4 years 3 months were secured for some 360 pairs only, but the evidence does not suggest that these were in any way selected. The results are given in tables and frequency diagrams. The health of the children has been previously reported on (*Brit. Med. J.*, 1953, i, 748); their development and behaviour will be described in a future paper.

As a group the premature children were about 2 lb. lighter at age 2 and about 2½ lb. lighter at age 4, and about 1 in. shorter at both ages. Nevertheless, by 2 years 31 per cent. of them had caught up with their controls in weight and 44 per cent. in height, and by 4 years 36 and 44 per cent.,

respectively. There was some indication that children of birthweight 4 lb. or less were more successful in catching up by 4 years than others.

Study of the heights and weights in 1952 of the mothers of some 280 pairs showed that the mothers of the premature children tended, on the average, to be lighter and shorter than those of the controls; but mothers of children that caught up by 4 years were of normal height and weight.

Although 30 per cent. of the premature children and 11 per cent. of their controls were stunted (31 in. or less at 2 years and 38 in. or less at 4 years) or underweight (25 lb. or less at 2 years and 33 lb. or less at 4 years) or both, they contributed only a small proportion of the children of this type in the whole recorded population.—W. M. Deans.

HAHN, L. **Heights and weights in schoolboys aged 11 and 14 years in the City of Leicester (including percentiles of heights and weights), 1950-52.** *Med. Officer*, 1954, 91, 105-108. [Dept. School Health, Leicester.]

In the years 1950 to 1952, 472 boys of 11 years and 1700 of 14 to 15 years entering or leaving 2 grammar schools and 8 secondary modern schools in Leicester were weighed and measured in gym shorts and without shoes. For height the range, mean and S.E., and S.D. were 47 to 64, 56.48 ± 0.12 , 2.52 and 48 to 72, 62.65 ± 0.09 , 3.6 in. for the younger and older groups; for weight the corresponding figures were 48 to 130, 76.48 ± 0.51 , 11.0 and 55 to 180, 103.57 ± 0.45 , 18.94 lb. The values in cm. and kg. are also given. The heights were slightly above those found by Daley (Abst. 2237, Vol. 18) for London boys. Boys leaving the grammar schools were on the average about 2 in. taller and over 10 lb. heavier than those from the secondary modern schools in the poorer districts, but even the latter surpassed the figures for London 14-year-olds in 1938.—W. M. Deans.

3472

GARDINER, P. A. **The relation of myopia to growth.** *Lancet*, 1954, 266, 476-479. [Miller Gen. Hosp., London.]

Analysis of the records of myopic schoolchildren, 122 boys and 296 girls, and of a comparable number of controls showed that the former were taller and heavier than normal children of the same age, and the more myopic they were, the greater was the difference. In myopic girls menarche tended to be early. There was evidence that the growth changes came before the onset of myopia. The nature of the connection, if any, remains obscure.—W. M. Deans.

3473

ROBERTS, D. F. **Body weight, race and climate.** *Amer. J. Phys. Anthropol.*, 1954, 11, 533-558. [Lab. Anthropol., Dept. Human Anat., Oxford.]

N.A. and R., July 1954

A survey was made of world anthropometrical and physiological literature and 116 samples of populations, containing from 20 to 3000 males between the ages of 20 and 40, were taken for mapping and statistical analysis; the mean weights and heights of these samples are given in an appendix.

There was a significant negative correlation ($r = -0.600$) between mean weight and mean annual temperature, and this still held ($r = -0.538$) when height was taken into account. The prediction formula for mean weight was

$$W = 0.071S - 0.199T - 48.1,$$

where W is weight in kg., S height in mm. and T mean annual temperature in degrees F. The short series of 33 samples available of measurements of women [details not given] yielded similar results. There were also differences between racial groups after the effects of height and temperature had been eliminated, the lowest weights being found in groups thought to have occupied a tropical habitat for a long time.

Because of the failure of many anthropometrical workers to collect weights, the data are so scanty that they must be interpreted with caution. Variation in weight with temperature may be an adaptation advantageous in the adjustment of heat production and heat exchange to external conditions, and it may be that "there is a general weight level for given climatic conditions about which actual weights vary according to socio-economic and nutritional standards". In any case, weight norms based on European standards should not be used indiscriminately in nutrition and growth studies of other races in other parts of the world.—W. M. Deans.

TOHARA, S. and MIYAKAWA, A. [Radiographical studies on the ossification of leg-bones in sheep.] *Bull. Nat. Inst. Agric. Sci., Chiba, Japan* [G], 1953, No. 7, 123-138. In Japanese: English summary.

Ossification of the leg bones of foetal and growing lambs was studied by X-rays.

All ossification centres of bone shafts appear from 1.5 to 2 months after conception and almost all centres at the ends of long bones between 3.5 and 5 months. At birth all ossification centres except that of the *sesamoides tertiae* are present if the foetus has developed normally. The ossification centres at the heads of the ulna and calcaneus are the last to appear and their absence at birth can be considered as indicative of faulty foetal development. Ossification centres at different parts of leg bones do not develop at the same rate. The times for completion of ossification of the ends of different bones are tabulated. (From summary.)—W. Godden.

RÖTTGER, H. Über den Wasserhaushalt in der physiologischen und toxischen Schwangerschaft. 1. Der Wasserhaushalt in der physiologischen Schwangerschaft. [Water metabolism in normal and toxæmic pregnancy. 1. Water metabolism in normal pregnancy.] *Arch. Gynäkol.*, 1953-54, **184**, 59-85. [Frauenklin., Med. Akad., Düsseldorf.]

The water volume of plasma and tissues was studied in 95 healthy women from the 2nd to the 10th month of pregnancy. Plasma volume was estimated photometrically after injection of a colloidal dye, and interstitial tissue water by the thiocyanate method. With advancing pregnancy, from about the 3rd month, a continuous increase was found in the water volume of both plasma and tissues. Plasma volume increased by 1093 ml. or 47.8 per cent., and extracellular water by about 4740 ml. or 35.7 per cent. Of the average body-weight increase during pregnancy, 49.3 per cent. is ascribed to increased water volume.

By the 9th day after delivery both plasma and extracellular water volume were considerably reduced, though not normal.—M. B. Richards.

3481

HUTCHINSON, D. L., PLENTL, A. A. and TAYLOR, H. C. (Jr.) The total body water and the water turnover in pregnancy studied with deuterium oxide as isotopic tracer. *J. Clin. Invest.*, 1954, **33**, 235-241. [Dept. Obstet., Coll. Phys. Surg., Columbia Univ., New York.]

Total body water was estimated at least once during pregnancy in 6 healthy women. In preliminary experiments it was found that the concentration of injected D_2O in serum reached equilibrium in from 2 to 3 hr. The constant for the curve of disappearance of D_2O from serum after initial equilibrium was found and from it the following values were calculated: total turnover = (total body water) (disappearance constant) (100); half-life time = 0.693/disappearance constant; turnover time = 1.00/disappearance constant.

During normal pregnancy there was an absolute rise in total body water and total solids. In the

early puerperium, as compared with early pregnancy, there was a relative loss of total body water and a relative gain in total body solids. In normal pregnancy, the disappearance constants and turnover rates were found to be within the limits reported for normal non-pregnant females. In patients with pre-eclampsia, water turnover rates were below normal and in hypertension they were normal or higher.—A. M. Thomson.

SANYAL, S. N. and GANGULY, A. K. Sterility effect of *Pisum sativum* (Linn). 8. Spectrophotometric study.

SANYAL, S. N. 9. Biological studies. 10. Chemical study. *Calcutta Med. J.*, 1953, **50**, 409-412; 413-414; 415-418. [Calcutta Bacteriol. Inst.]

For earlier parts, see Absts. 288, 2437, Vol. 21; 2621, Vol. 22; 2074, Vol. 23.

8. Ultraviolet spectrophotometric studies of the action of *m*-xylohydroquinone have been extended with pure progesterone and pregnanediol made available since the earlier work. Progesterone is reduced by *m*-xylohydroquinone but vitamin E counteracts the effect.

9. Experiments on female rats were repeated with *m*-xylohydroquinone in place of oil of *Pisum sativum* used in earlier investigations (Abst. 288, Vol. 21). When given within 8 days of conception it caused death and resorption of foetuses; when given after the 10th day of gestation there was no effect and normal young were born. The adverse effect was counteracted when vitamin E was given along with the *m*-xylohydroquinone in the early stage.

10. The diacetyl and monobenzoyl compounds of *m*-xylohydroquinone were prepared by methods which are described and were given to immature female rats. It was found that the diacetyl compound is stable but the monobenzoyl is easily broken down to liberate the *m*-xylohydroquinone. There was no evidence of toxicity.—D. Harvey.

NIKITIN, V. N., TVERDUN, O. G. and DOKTOROVICH, N. L. Periodika sekretornogo protsessa v vyeni. [The periodicity of milk secretion of the udder.] *Zh. Obshchei Biol.*, 1953, **14**, 275–289. [Ukrain. Inst. Zhivot.]

A new concept is advanced for the active regulation of the capacity of the udder by the nervous system, and for the significance of nervous receptors in the udder in the process of milk secretion. As a working hypothesis it is assumed that the formation of milk and particularly of milk fat after milking depends on the total increase in the "trophic tone" of the udder and on centres in the central nervous system. The partial removal of the layer of fat globules adsorbed on the alveolar epithelium which occurs during milking may have additional significance. A decrease in the rate of milk secretion, particularly that of fat, before milking depends on a decrease in the nervous impulses and also on the accumulation of fat globules on the alveolar epithelium.—W. Hughes.

FOURNIER, P. and SUSBIELLE, H. Étude de l'influence de la lactation sur l'état des os longs de la rate. [Effect of lactation on the long bones of the rat.] *J. Physiol., Paris*, 1953, **45**, 547–558. [Lab. Physiol. Nutrit., École Hautes-Études, Paris.]

Female rats aged about 7 months, which had had one litter, received daily 13 g. of a diet supplying 500 mg. Ca and 500 mg. P per 100 g. diet. Lactating females received a high-energy supplement. The 6 initial controls were killed on the day on which the 5 experimental rats were mated. The latter had litters which were weaned at 21 days, when the mothers and 6 further unmated controls were killed.

The long bones of the lactating group had a mean total weight of 1068 mg., compared with 1301 and 1386 mg. for initial and final controls, respectively, a highly significant loss. The loss from the femur was 27, from the tibia 20 and from the humerus 19 per cent. The losses of Ca and P were also about 23 per cent., the ratio remaining unchanged, as in the main did the percentage Ca and P composition of the bones. The loss of bone tissue is therefore one of resorption and not of demineralisation. The process of resorption is discussed, and it is concluded from the results of other work that when Ca intake is insufficient resorption may be accompanied by demineralisation.

Vol. 24, No. 3

tion. It is thought premature to conclude from existing work that the skeletal loss is inevitable.

D. Duncan.

3487

FOURNIER, P., SUSBIELLE, H. and BOURDEAU, A. Effet du régime alimentaire sur l'état du squelette de la rate en lactation. [Effect of diet on the skeleton of the rat during lactation.] *J. Physiol., Paris*, 1953, **45**, 655–662. [Lab. Physiol. Nutrit., École Hautes-Études, Paris.]

The rats were 7 months old at the beginning of the experiment and each had had one litter. Eight were unmated as controls and the rest were mated and divided into 2 groups of 6 and one of 7. After parturition they received the experimental diets, given to appetite. The first was that used in an earlier experiment (see preceding Abst.), the second supplied similar amounts of the principal nutrients but contained a considerable proportion of dried and fresh milk; the third was high in energy value, and contained 36 per cent. protein and 17.2 per cent. fat. All 3 contained the same amounts of Ca and P, and each contained TiO_2 . At the end of lactation the weights of the femurs, tibiae and humeri were compared with those of the unmated rats.

The rats on the ordinary and high-energy diets lost in 20 days of lactation 17 and 19 per cent., respectively, of the weight of the long bones, but those on the milk diet lost only 8 per cent. The losses of bone tissue per young rat reared were 28, 31 and 13 mg., respectively. The protective effect of milk was thus considerable.—D. Duncan.

3488

FOURNIER, P., SUSBIELLE, H. and BOURDEAU, A. Influence de la composition du régime sur le métabolisme calcique de la rate allaitante. Contribution à l'étude de la physiologie de l'os. [Effect of the composition of the diet on calcium metabolism of the lactating rat. Contribution to the study of the physiology of bone.] *J. Physiol., Paris*, 1953, **45**, 723–737. [Lab. Physiol. Nutrit., École Hautes-Études, Paris.]

The rats were those described in the preceding Abstract.

The Ca content of the litters at weaning, assuming equal utilisation of the milk by all the young, indicated the total amount of Ca secreted in the milk; it was not significantly different in the 3 groups. The urinary output of Ca was small, and the greater part of the Ca absorbed was eliminated in the milk. The net absorption of Ca was 2.21 g. in the rats on milk diet, and 2.02 and 1.90 g., respectively, on the ordinary and high-energy diets. The daily absorption increased steadily from about 7 mg. before parturition to 190 mg. at the end of lactation. The coefficient of absorption also increased, especially in the rats on milk diet.

The mean Ca balance was negative in all groups, but least on milk diet, in which group 3 of the 7 rats had positive balances.

The mechanism of the protective effect of milk is discussed, and its value is ascribed to the presence of lactose.—D. Duncan.

3489

FOURNIER, P. and SUSBIELLE, H. Le comportement des os longs de la rate pendant la lactation. Influence de la quantité ingérée de régime équilibré. [**Behaviour of the long bones of the rat during lactation. Effect of the amount of a balanced diet ingested.**] *C.R. Soc. Biol.*, 1953, **147**, 1588-1591. [Lab. Physiol. Nutrit., École Hautes-Études, Paris.]

Rats aged 7 months were given during second pregnancy and lactation a well-balanced diet; one group was allowed the diet to appetite, the other group received 13 g. per rat daily, with a carbohydrate supplement to supply energy needs during lactation. The first group ate about 40 g. per rat daily, and had thus about three times as much mineral, protein and B vitamins as the others.

At weaning the restricted rats had lost on the average 21 g. bodyweight, but the unrestricted rats had gained about 4 g. Their litters weighed on the average 191 and 327 g., respectively. The loss of weight from the long bones was 23 and 19.3 per cent., respectively, or 35 and 30 mg. for each young rat weaned.

It is concluded that the loss of skeletal weight during lactation is little influenced by the intake of minerals, protein or vitamins of the B complex.

D. Duncan.

3490

FOURNIER, P. Nature et conséquences du prélèvement effectué par la rate allaitante sur son squelette. [**Nature and effects of resorption from the skeleton of the lactating rat.**] *C.R. Acad. Sci.*, 1954, **238**, 270-272.

See above Absts. The author again insists that it is premature to conclude that the loss of skeletal weight during lactation is inevitable.—D. Duncan.

3491

FOURNIER, P. L'effet protecteur du lait vis-à-vis de la résorption des os de la rate allaitante. [**Protective effect of milk against bone resorption in the lactating rat.**] *C.R. Acad. Sci.*, 1954, **238**, 391-393.

In continuation of earlier work (see above Absts.) rats were pair-fed. Group 1 received to appetite an ordinary diet based on wheat and casein, group 2 received equivalent quantities of the principal nutrients in the form of a diet based on milk.

After a lactation rats of group 1 had long bones weighing 17 per cent. less than those of non-lac-

tating controls, and contained 19 per cent. less total Ca, representing a loss of 330 mg. The losses in group 2 were 8 and 4 per cent. and 70 mg., respectively.

It is concluded that milk contains some substances which affects bone metabolism in such a way as to reduce the drain due to lactation.

D. Duncan.

3492

FOURNIER, P. L'effet protecteur du lactose vis-à-vis du squelette de la rate allaitante. [**Protective effect of lactose on the skeleton of the lactating rat.**] *C.R. Acad. Sci.*, 1954, **238**, 509-511.

Two groups of rats received to appetite during lactation diets with a basis of wheat and casein, the difference being that one contained 12 per cent. starch and the other 12 per cent. lactose.

The rats on the ordinary diet lost in 19 days of lactation 250 mg. Ca on the average, about 15 per cent. of the total Ca of non-lactating controls. Seven of the 8 rats had strongly negative Ca balances; the eighth was in equilibrium. The lactose diet completely prevented this loss of Ca, rats gaining on the average 18 mg. Ca during the lactation. Two had slightly negative balances, 2 were in equilibrium and 3 had positive balances.

The means by which lactose exerts this favourable influence are not understood.—D. Duncan.

HAWKING, F. **Milk, *p*-aminobenzoate, and malaria of rats and monkeys.** *Brit. Med. J.*, 1954, **i**, 425-429. [Nat. Inst. Med. Res., Mill Hill, London, N.W. 7.]

For the preliminary communication see Abst. 4301, Vol. 23.

Suppression of *Plasmodium berghei* infection by milk diet was more effective in rats weighing 200 g. than in younger animals. Chloramphenicol, 1 in 20,000, or folic acid, 1 in 10,000, or *p*-aminobenzoate, 1 in 40,000, added to the milk allowed the malaria infection to develop as well as in rats on stock diet. Smaller concentrations of *p*-aminobenzoate were sometimes effective. Methion-

ine, *p*-hydroxybenzoate and vitamin B_{12} were ineffective.

Plasmodium knowlesi infection failed to develop in a monkey on milk diet, but developed in 2 others which received *p*-aminobenzoate, 1 in 10,000 and 1 in 1 million, respectively, in the milk.

In suckling rats *P. berghei* infections developed much more rapidly and intensely when *p*-aminobenzoate was supplied by intraperitoneal injection to the babies or the mother or was smeared on the mother's nipples. Similar results were obtained for breast- or bottle-fed baby monkeys with *P. cynomolgi* infection.

The functions of *p*-aminobenzoate are discussed. It is suggested that the relative immunity to malaria of babies in the tropics may be due to deficiency of *p*-aminobenzoate in breast milk.

D. Duncan.

RAMAKRISHNAN, S. P. **Studies on *Plasmodium berghei* N. Sp. Vincke and Lips, 1948. 8. The course of blood-induced infection in starved albino rats.**

RAMAKRISHNAN, S. P., PRAKASH, S., KRISHNASWAMI, A. K. and SINGH, C. **9. Effect of milk diet on the course of blood-induced infection in albino rats.** *Indian J. Malariol.*, 1953, **7**, 53-60; 61-65. [Malaria Inst. India, Delhi.]

8. Adult rats were starved for from 5 to 10 days and were inoculated with one million parasites on the first or sixth day. Others were inoculated and maintained on a standard diet. After the fast they were fed and watched for another 16 days. Parasites were counted in the blood at regular intervals.

The development of the parasites was adversely affected by the host's fasting, and after 10 days' starvation with inoculation on the first day none ever appeared; after 5 days' starvation with inoculation on the first day they appeared and

were present for 10 days. When the inoculation took place after 5 days' fasting no parasite ever appeared, but when such an inoculation was followed at once by feeding, the parasites developed normally after a slow start. Alternating periods of 5 days' fasting and feeding caused the infection to become latent.

In younger rats the inhibiting effect of starvation was less.—E. M. Hume.

9. Small groups of rats were fed on a whole diet of milk or on diets of the same energy value, one containing some milk, the other none. The animals were fed on the milk diet or the stock diet for a week before being inoculated and allotted to the different diets. In the blood of the rats on the pure milk diet the parasites persisted for a shorter time, and the average parasite count and peak count were lower, than in the blood of the animals on the other diets; consumption of the milk diet beforehand enhanced the effect. It is suggested that for optimum multiplication malarial parasites in rats require some substance or substances not present in milk.—L. Wills.

LONG, D. A. Influence of protein metabolism on bacterial allergy. Its relation to cortisone desensitisation. *Lancet*, 1954, **266**, 231-234. [Nat. Inst. Med. Res., London.]

Groups of 10 guineapigs were fed on Bruce and Parkes' diet 18 (Abst. 138, Vol. 17) or on this diet with 5 per cent. skimmed milk replacing part of the grassmeal (diet 18A), with or without unlimited cabbage. They were injected with B.C.G. vaccine and their sensitivity to tuberculin was estimated.

Diet 18 is deficient in ascorbic acid, but diet 18A produced no evidence of deficiency after 4 months. Cortisone injected 6 hr. before the tuberculin depressed sensitivity in animals on diet 18 but not

in those on 18A. Additional ascorbic acid, purified or in cabbage, had a slight effect alone, but a large effect in the presence of cortisone. The skimmed milk in diet 18A antagonised desensitisation by ascorbic acid, and methionine added to diet 18 had a similar effect. Ethionine facilitated desensitisation by ascorbic acid, but this in turn was inhibited by reduced glutathione. Ethionine did not influence sensitivity in ascorbic acid deficiency.

The analogy between the actions of cortisone and of alloxan is discussed. The hypothesis is put forward that cortisone interferes with glutathione formation in the course of a general interference with protein synthesis; the resulting fall in glutathione facilitates the oxidation of ascorbic acid to dehydroascorbic acid, the latter inactivating phosphoglucomutase and increasing the tissue concentration of glucose-1-phosphate, intimately concerned with desensitisation.—D. Duncan.

MACLEOD, R. A. and BRUMWELL, C. Cellulose digestion by rumen micro-organisms and its stimulation by fishery by-products. *Fish. Res. Board Canada, Progr. Rep. Pacific Coast Stat.*, 1953, No. 96, 16-20. [Pacific Fish. Exp. Stat.]

The addition of whale or herring solubles to cellulose fermenting in media inoculated with rumen contents increased its digestion to the same extent as did a mixture of 18 amino-acids. N was maintained at a level of 24 mg. in 40 ml., the pH was kept between 6.8 and 7.0 and incubations lasted for from 70 to 120 hr. [apparently under aerobic conditions].—A. T. Phillipson.

3506

LEWIS, D. The reduction of sulphate in the rumen of the sheep. *Biochem. J.*, 1954, **56**, 391-399.

N.A. and R., July 1954

[Agric. Res. Counc. Unit Microbiol., Univ. Sheffield.]

Reduction of sulphate to sulphide was shown to occur in the rumen of the sheep and in washed suspensions of mixed rumen bacteria *in vitro*. Both in the sheep and *in vitro* repeated additions of sulphate resulted in formation of concentrations of sulphide. The optimum pH for the reaction was 6.5. Sulphite and thiosulphite were similarly reduced, with H uptake and sulphide production within the range of 70 to 100 per cent. of the theoretical values. Glucose, formate, fructose, lactate, pyruvate, succinate, ethanol, citrate and malate proved to be hydrogen donors, as well as H₂ gas. After fractionation of the rumen bacteria, the smaller organisms caused more rapid reduction than the larger.—A. T. Phillipson.

3507

PRIER, J. E. **Studies on toxic factors produced by rumen microorganisms of sheep.** *Amer. J. Vet. Res.*, 1954, **15**, 51–54. [Dept. Vet. Sci. Bacteriol., Wyoming Agric. Exp. Stat., Laramie.]

Rumen samples were taken from sheep, alive or dead, which had shown clinical signs of indigestion. Cultures were made in a fluid thiol (Difco) medium. After 10 to 12 days' incubation the medium was filtered off. Single colonies were picked off from agar plates grown in the same medium. The effects obtained from pure or mixed cultures that produced physiologically active substances were either an increase of 10 to 100 or a decrease of 20 to 140 mm. Hg in the blood pressure of sheep and dogs.—A. T. Phillipson.

3508

RAVEL, J. M., WOODS, L., FELSING, B. and SHIVE, W. **Some interrelationships of aspartic acid, threonine, and lysine.** *J. Biol. Chem.*, 1954, **206**, 391–400. [Biochem. Inst., Univ. Texas, Austin.]

In the presence of biotin, lysine, threonine and bicarbonate *Lactobacillus arabinosus* did not require aspartic acid for growth. In the absence of these substances, Tween 80 being substituted for biotin, aspartic acid was required; the requirement was reduced by any one or, better, by a combination of two or more of these substances. With *L. casei* results were similar, except that lysine was indispensable at all times.

Lysine, threonine or both together were, in that order, increasingly effective in protecting *L. arabinosus* against the inhibition of aspartic acid utilisation produced by cysteic acid; similar results were obtained with threonine and *L. casei*.

Threonine was about twice as effective as *allo*-threonine and 5 or 10 times as effective as homo-serine or the lactone of γ -hydroxy- α -ketobutyric

acid in replacing aspartic acid for both organisms; succinic, fumaric, malic and oxaloacetic acids were ineffective. Asparagine could replace aspartic acid for *L. casei*, but not to any extent for *L. arabinosus*.

Biocytin, α - ϵ -diaminopimelic acid, α -amino-adipic acid or α -amino- ϵ -hydroxycaproic acid did not replace lysine.—C. Warner.

GYÖRGY, P., NORRIS, R. F. and ROSE, C. S. ***Bifidus* factor. 1. A variant of *Lactobacillus bifidus* requiring a special growth factor.**

GYÖRGY, P., KUHN, R., ROSE, C. S. and ZILLIKEN, F. **2. Its occurrence in milk from different species and in other natural products.**

GYÖRGY, P., HOOVER, J. R. E., KUHN, R. and ROSE, C. S. **3. The rate of dialysis.**

GAUHE, A., GYÖRGY, P., HOOVER, J. R. E., KUHN, R., ROSE, C. S., RUELIUS, H. W. and ZILLIKEN, F. **4. Preparations obtained from human milk.** *Arch. Biochem. Biophys.*, 1954, **48**, 193–201; 202–208; 209–213; 214–224. [Dept. Paediat., Univ. Pennsylvania, Philadelphia.]

1. *Lactobacillus bifidus* var. *Penn*, which requires an unknown growth factor present in human milk, was shown to be morphologically identical with but serologically different from the regular strains of *L. bifidus* tested. The metabolic pattern of the strains was the same except for the requirement of the human milk growth factor and the inability of the variant to use maltose in place of lactose for growth.

2. Relatively good sources of the growth factor were human and rat's colostrum, human milk, rat's milk, cow's and sow's colostrum and cat's milk. Poor sources were the milk of ruminants, cow, ewe and goat. The potencies of milks of monkey, dog, donkey, rabbit, mare and sow were intermediate. The growth factor was found in high concentration in human saliva, semen, amniotic fluid, meconium and tears. Pig gastric mucin was a rich source. Ammonium salts, *N*-acetylglucosamine and *N*-acetylgalactosamine were active.

3. The growth factor could be separated into a dialysable fraction having from 40 to 75 per cent. of the activity and a relatively non-dialysable fraction of 25 to 60 per cent.

4. Cream, proteins, salts and lactose were removed and bifidus-active N-containing oligo- and polysaccharides were obtained from the lactose-free active concentrates. By chromatography 4 different active components were found; all contained *N*-acetylglucosamine. Three were laevorotatory. N-free saccharides obtained from the lactose-free concentrates were inactive.

TOMARELLI, R. M., HASSINEN, J. B., ECKHARDT, E. R., CLARK, R. H. and BERNHART, F. W. **The isolation of a crystalline growth factor for a strain of *Lactobacillus bifidus*.** *Arch. Biochem. Biophys.*, 1954, **48**, 225-232. [Wyeth Labs., Inc., Nutrit. Div., Mason, Mich.]

Seven strains of *Lactobacillus bifidus* which required an unknown growth factor present in human milk but not in enzymic digest of casein were isolated. The relative growth-promoting activities of human milk and other substances for one of these strains are tabulated. Pig gastric mucin was a rich source. From the acid-hydrolysed mucin was isolated an active disaccharide tentatively identified as galactose-acetylglucosaminide.—F. C. Aitken.

KOROTKOVA, G. P. O toksicheskikh svoistvakh "belka" i "lizotsima" kurinova yaitsa.

[Toxic properties of white and lysozyme of the hen's egg.] *Dokl. Akad. Nauk. S.S.S.R.*, 1953, **92**, 197-200. [Leningrad Gosud. Univ.]

The effect of egg white and lysozyme extracted from it was studied on *Glaucoma scintillans* and *Paramecium caudatum*. It was found that the paramecium died in the white on the average in 27.8 min. and *Glaucoma* in 6.3 min.; the corresponding times for lysozyme were 14.8 and 8.5 min. There were differences in the morphological changes accompanying the death of the ciliates in the white and in lysozyme. White and lysozyme from eggs laid during the spring and summer were more toxic than those from eggs laid in autumn and winter. The highest toxicity was shown by liquid white from the inner layer, in which *Glaucoma* lived only 4.44 ± 0.32 min. Large variations in the toxicity of the white and lysozyme were also shown for *Trichomonas vaginalis*, *Lambliia intestinalis*, *Pelmatohydra olygactis*, *Aeolosoma*, *Physa fontinalis*, rat spermatozoa, zoospores of *Phytophthora infestans* and *Elodea* leaves. The white is not toxic to the tissue of the chick embryo itself. It is concluded that the white and the lysozyme prepared from it are not identical in their effects.

MISCELLANEOUS FEEDING EXPERIMENTS

3513

GRIFFITHS, W. J. (Jr.) and GALLAGHER, T. J. **Differential dietary choices of albino rats occasioned by swimming.** *Science*, 1953, **118**, 780. [Dept. Psychol., Univ. Mississippi, Oxford.]

For 14 days rats were allowed to swim for about 1 hr. 50 min. daily or until distress was evident. During this and a preliminary period without swimming they had access to solutions of glucose and saccharine. During the exercise period they increased significantly their intake of glucose and decreased, by an amount not statistically significant, that of saccharine.—D. Harvey.

3514

BALDISSERA NORDIO, C. **Variazioni emocitometriche nei ratti trattati con *Allium cepa*.** [Variations in the numbers of blood cells from rats treated with *Allium cepa*.] *Boll. Soc. ital. sper.*, 1953, **29**, 985-986. [Ist. Zootec. Gen., Fac. Agrar., Univ. Milan.]

Eight rats fed on a mixture of grains were given in addition 6 or 20 g. cooked onion per kg. body-weight daily for 20 days. Every 3 days blood counts were made and Hb was estimated. The percentage of Hb and the number of red cells

diminished, and hyperchromic anaemia was established. There was little change in the white cell count.—E. M. Hume.

3515

REID, M. E. and BRIGGS, G. M. **Development of a semi-synthetic diet for young guinea pigs.** *J. Nutrition*, 1953, **51**, 341-354. [Nat. Inst. Arthritis Metabol. Dis., Nat. Inst. Health, Bethesda, Md.]

A semi-synthetic diet based on casein, maize oil, sucrose, cellophane, maize starch, cerelose, K acetate, MgO, salts and vitamins has been developed for guineapigs. It has a greater variety of carbohydrates and a higher content of vitamins and minerals than diets previously used. Animals given the diet at from 2 to 4 days of age and maintained on it to 150 days grew almost as well as those on a good commercial pelleted diet, and were normal in weight, general appearance, physical activity, appearance and weight of internal organs, haematocrit and granulocyte and total leucocyte counts. Preliminary results indicate that the diet supports reproduction, although it appears to be less satisfactory for this function than for growth. The diet can be used for evaluating vitamin requirements.—M. B. Richards.

ABBOTT, O. D., FRENCH, R. B. and TOWNSEND, R. O. Effect of processing upon the nutritive value of milk as evaluated with rats. *Florida Agric. Exp. Stat. Bull.* No. 485, November 1951, pp. 12.

The milks tested were raw and pasteurised, obtained from 2 sources and fresh or aged for 4 days; non-fat milk solids fresh or aged for several summer months without refrigeration; and evaporated milk. They were given to weanling albino rats in groups of 6 for from 10 to 13 weeks in a diet consisting of two-thirds ground whole hard spring wheat and one-third milk. Vitamin A and fat were added to the diets containing non-fat milk solids to bring the levels to those in whole fluid milk.

The results are presented in graphs. On the basis of weight, reproductive performance and skeletal mineralisation in the rats, no significant difference was found in the nutritive values of the milks. The nutritive value of whole milk from one source was reduced by unidentified factors not related to the processing, and not destroyed by pasteurisation. The nutritive value of the non-fat milk solids diet was reduced when aged solids were given with slightly rancid vegetable oil. Butter could successfully replace vegetable oil in the non-fat milk solids diet.—P. C. Jowsey.

3518

ABBOTT, O. D., FRENCH, R. B. and TOWNSEND, R. O. The nutritive value of various breads and supplements in experiments with white rats. *Florida Agric. Exp. Stat. Bull.* No. 483, September 1951, pp. 22.

Five breads were used: water bread (unenriched white bread); enriched water bread (enriched according to the present regulations); milk bread (white bread containing 6 per cent. non-fat milk solids by weight of flour and unenriched); enriched milk bread; and whole wheat bread made from 100 per cent. extraction flour, without milk.

The composition of the 5 breads, in the above order, was: crude protein 13.05, 13.16, 14.00, 14.00, 15.14; ash 1.83, 1.84, 2.94, 2.94, 3.34 [presumably

Vol. 24, No. 3

per cent. but not stated]; vitamin B₁ 0.29, 1.36, 0.29, 1.36, 1.75; riboflavin 1.55, 2.35, 1.74, 2.54, 0.80; nicotinic acid 6.01, 17.64, 5.13, 17.17, 17.80 mg. [per 100 g.?] all on an 8.2 per cent. moisture basis.

In all the feeding experiments with 3-week-old albino rats, one control group received a stock diet and the other groups each had one of the breads plus fat to bring the fat content of the diet to 10 per cent., and vitamin A at the rate of 200 I.U. per rat daily.

In the first test, the mothers received a water bread diet when the young were from 12 to 15 days old. The quality of the milk appeared to be affected, and at 21 days the young weighed on the average 32 g. instead of the 38 to 40 g. usual for this age. After 13 weeks on the test diets young rats given whole wheat or either type of milk bread were superior in size and condition to the rats given the water breads, but were not comparable to those given the stock diet. It was thought that the water bread diet of the mothers during lactation may have contributed to this result, and in a second experiment the mothers were allowed stock diet until the young were placed on test at 21 days of age. The results were similar to those of the first test, and no significant advantage of enrichment could be demonstrated.

Supplementation of the 2 water breads with protein in the form of non-fat milk solids to levels of 15.3 and 18.0 per cent. resulted in more normal growth curves, but even then no advantage of enrichment could be demonstrated.

The limiting factor in bread appeared to be protein, but tests with purified casein showed that some substance which makes possible the more effective utilisation of protein had been removed in purification. Aureomycin and vitamin B₁₂ supplied this, and rats given this supplement with a diet of water bread and casein grew better than those given the diet of water bread and casein alone.

The lack of response to the standard enrichment of water bread indicated that enrichment is of doubtful value, but it is considered that the enrichment of bread with non-fat milk solids should be further investigated.—P. C. Jowsey.

3519

WOMACK, M., MARSHALL, M. W. and SUMMERS, J. C. Cottonseed food supplement. Nutritive value of bread and cookies containing cottonseed flour. *J. Agric. Food Chem.*, 1954, 2, 138-140. [Bur. Human Nutrit., Agric. Res. Admin., U.S. Dept. Agric., Washington 25, D.C.]

Breads or cookies were given as sole source of protein to groups of 12 weanling littermate rats.

for 28 days. Bread made from 10 parts cottonseed flour to 100 parts white wheat flour gave greater gains than equal amounts of bread made without cottonseed flour. Nitrogen efficiency was greater with the cottonseed flour bread when the breads yielded a 10 per cent. protein level in the ration. Bread made with 4 parts non-fat milk solids and 8 parts cottonseed flour to 100 parts white flour gave greater gains in weight than equal amounts of bread made with milk solids and without cottonseed flour. Nitrogen efficiencies were not significantly different at the 10 per cent. protein level.

Growth of rats given cookies of oatmeal and white flour with or without cottonseed flour replacing 21.5 parts of the flour was poor.

SUBRAHMANYAN, V., MURTHY, H. B. N. and SWAMINATHAN, M. **Effect of partial replacement of rice, wheat or ragi (*Eleusine coracana*) by tuber flours on the nutritive value of poor vegetarian diets.** *Brit. J. Nutrition*, 1954, **8**, 1-10. [Central Food Technol. Res. Inst., Mysore.]

Groups of 6 rats about 4 weeks old and weighing from 40 to 55 g. were given diets containing raw milled rice, whole wheat flour, or ragi (*Eleusine coracana*) 75, tur dhal (*Cajanus indicus*) 5, potato and brinjal (*Solanum melongena*) 8.2, *Amaranthus gangeticus* 2.1, groundnut oil 5.0, milk powder 0.9 and salt 0.3 per cent., or the same with 25 per cent. of the cereal replaced by tapioca flour, sweet potato flour, a 4:1 mixture of sweet potato flour and groundnut cake flour, or a 4:1 mixture of tapioca flour and groundnut cake flour.

Average weekly weight gains were significantly improved by all 4 substitutes for 25 per cent. of rice, by all except sweet potato flour for 25 per cent. of wheat, and by the groundnut cake mixtures for 25 per cent. of ragi. The rice-tapioca result was confirmed with different samples of rice and tapioca. In paired feeding tests the difference between rice and tapioca and rice alone was not significant. Further experiments suggested that the beneficial effect of tapioca was due to the extra Ca it supplied, and balance experiments showed that on the average rats on the rice-tapioca diet retained significantly more Ca than those on the rice diet, the differences being 6 mg. and 4 mg. weekly for feeding to appetite and paired feeding, respectively. When the diets were given to appetite there was little difference in N retention, but with paired feeding N retention was less on the rice-tapioca diet than on the rice diet. Even a 50:50 mixture of rice and tapioca gave significantly better weight gains than rice alone, provided the diets were given to appetite.—W. M. Deans.

3521

HARRIS, L. E., HARRIS, J. R., MANGELSON, F. L., GREENWOOD, D. A., BIDDULPH, C., BINNS, W. and MINER, M. L. **Effect of feeding DDT-treated alfalfa hay to swine and of feeding the swine tissues to rats.** *J. Nutrition*, 1953, **51**, 491-505. [Utah Agric. Exp. Stat., Utah State Agric. Coll., Logan.]

Four plots of alfalfa hay were dusted with 20 lb. per acre of 10 per cent. DDT dust 14 days before the crop was cut for hay, which was sun-cured and baled. Corresponding plots, untreated, were harvested in the same way. Weanling pigs were given a ration of ground barley, soya bean meal, dried whey, fish meal, tankage, salt and shark liver oil concentrate. For different groups up to 33 per cent. of treated or untreated hay replaced a corresponding amount of barley. The treated hay contained 23 p.p.m. DDT on a dry matter basis. At the highest hay intake the DDT had no effect on the rate of growth, feed utilisation or health of the pigs up to the time of slaughter at 210 lb. liveweight.

Samples of raw fat, cured bacon and cured shoulder from the control and experimental pigs were given to weanling rats on an otherwise normal ration for 14 weeks, the DDT in the diets averaging on a dry matter basis 2.2, 2.3 and 5.3 p.p.m. when the fat, bacon and shoulder came from pigs fed on treated hay. DDT in the diet did not influence gain in bodyweight or food consumption. All the animals and tissues were normal at post-mortem examination.—W. Godden.

3522

ELLIOTT, H. C. (Jr.) and PIGMAN, W. **The effect of a typical infant's diet on the caries incidence of the Syrian hamster.** *J. Dent. Res.*, 1954, **33**, 27-32. [Dept. Biochem., Dent. Sch., Univ. Alabama, Birmingham.]

Hamsters weaned at 17 days old were given for 58 days a laboratory chow diet with 28.2 per cent., or other synthetic diets with 78.2, 70.5, 74.0 or 61.8 per cent., water-soluble carbohydrates. Of these the last was a common infant feeding mixture, 38 per cent. Dextri-Maltose and 62 per cent. powdered whole milk.

The findings of earlier workers were confirmed regarding the caries-producing effects of diets rich in water-soluble carbohydrates, but next to the chow diet the infant food had the smallest effect. It is suggested that all carbohydrates are not equal in their caries-producing power.—D. Harvey.

3523

PEREZ-TAMAYO, R., MURPHY, W. R. and IHEN, M. **Effect of cortisone and partial starvation on liver regeneration.** *Arch. Pathol.*, 1953,

N.A. and R., July 1954

56, 629-636. [Dept. Pathol., Sch. Med., Washington Univ., St. Louis, Mo.]

Rats received a stock diet to appetite or in restricted amounts to bring about loss of weight. Those of 3 groups of 20 were subjected to partial hepatectomy, the other 3 groups to control laparotomy.

Cortisone inhibited liver regeneration; the number of cells regenerated was less but their size was greater. In animals losing weight on restricted food intake, cortisone tended to maintain liver weight. Restricted food intake failed to inhibit liver regeneration.—D. Duncan.

CARTER, M. W., SMART, W. W. G. (Jr.) and MATRONE, G. Estimation of estrogenic activity of genistein obtained from soybean meal. *Proc. Soc. Exp. Biol. Med.*, 1953, **84**, 506-507. [Animal Nutrit. Sect., Dept. Animal Indust., N. Carolina Agric. Exp. Stat., Raleigh.]

Genistein isolated from solvent-extracted soya bean meal was found with immature mice to be 4.44×10^{-6} times as potent as diethylstilboestrol in oestrogenic activity. The meal itself was also active.—D. Harvey.

3526

SHILS, M. E. and GOLDWATER, L. J. Effect of diet on the susceptibility of the rat to poisoning by 2, 4-dinitrotoluene. *Arch. Indust. Hyg.*, 1953, **8**, 262-267. [Dept. Occupational Med., Sch. Pub. Health, Columbia Univ.]

Four diets containing casein, maize oil, glucose, minerals and vitamins, constructed to provide a low protein and high fat intake, or low protein and low fat, or moderate protein and high fat, or moderate protein and low fat, were given to comparable groups of albino rats with or without addition of 2:4-dinitrotoluene. Difficulty was experienced in obtaining equal intakes of dinitrotoluene when it was incorporated in the diet, so further tests were made with the substance administered parenterally. With low-protein diets a high intake of fat appeared to protect the animals against the toxic substance. With moderate protein intake the lethal effect of dinitrotoluene was always prevented. The drug decreased growth on all the diets, but less with diets containing moderate amounts of protein.—A. M. Copping.

COHEN, E. A comparison of the total protein and albumin content of the blood sera of some reptiles. *Science*, 1954, **119**, 98-99. [Dept. Zool., Rutgers Univ., New Brunswick, N.J.]

Total protein and albumin were estimated by the biuret method of Gornall *et al.* (Abst. 1695, Vol. 19) in the blood sera of 13 species of snake and 6 of turtle.

The results are presented in detail. There was no significant difference in total protein between snakes and turtles; albumin content differed significantly.—P. C. Jowsey.

3529

CHURÝ, Z. Některé haematologické údaje u hladovějící ropuchy zelené (*Bufo viridis*).

Vol. 24, No. 3

[Some haematological data in the fasting green toad (*Bufo viridis*).] *Scripta med.*, 1952, **25**, 23-30. [Inst. Gen. Exp. Pathol., Masaryk Univ., Brno.] English and Russian summaries.

The blood picture was studied in *Bufo viridis* fasted for 2 to 6 weeks at the beginning of summer. The average counts were erythrocytes 479,000, leucocytes 7000 and platelets 9000 per c. mm.; the average size of erythrocytes was $16.7 \times 13.0 \mu$. Erythroblasts were found in the peripheral blood, and polychromatophilia with relative and absolute lymphocytosis combined with neutropenia and monopenia occurred during fasting. Lymphocytosis and the occurrence of erythroblasts might be explained by reduced activity of endocrine glands and the vegetative nervous system.

M. Prokšová (Czechoslovakia).

3530

NEBOLSINA, T. K. Pitanie mal'kov i leshcha v severnom Kaspii. [The nutrition of juvenile roach and bream in the northern Caspian.] *Dokl. Akad. Nauk S.S.S.R.*, 1953, **91**, 1225-1228. [Kasp. Bassein. Filial., Vses. Nauch.

Issled. Inst. Morsk. Ryb. Khoz. i. Okeanografiya.]

The intestines of 905 young roach and 542 bream from the northern Caspian were examined in 1949. Young roach feed on organisms living on the sea bed, mainly molluscs and crustaceans; the food of the young bream is crustaceans, zooplankton (Cladocera and Copepoda) and worms. The differences in the food of young roach and bream of different lengths were trifling.

JANČÁŘEK, A. Příspěvek k fyziologii kapří digesce: Trávení bílkovin. [The physiology of digestion in the carp: digestion of proteins.] *Sborn. Vysoké Šk. Zeměd.*, 1949, **41D**, 1-60. [Sch. Agric., Univ. Brno.] English and Russian summaries.

The proteolytic activity of intestinal liquor, bile, extracts of liver and pancreas and intestinal tissue were studied by a modification of the methods of Gautier, Roche and Baratte. Extracts were also examined of the bodies of some animals forming the natural food of the carp: Tubificidae, Daphnidae, Lumbricidae, Ostracoda and mosquito larvae (*Culex*).

The intestinal liquor had the highest absolute protease activity. At temperatures between 10° and 50° C. the bile, liver and pancreas showed similar curves of activity. The curves of activity of diluted intestinal liquor and intestinal tissue at different temperatures were strikingly continuous and similar, probably because of integration of the activity of a series of enzymes. The extracts of liver and pancreas were activated by those of the intestinal mucosa or contents, the latter being more effective. It is considered that the greater effect of the contents was due to the enzymic components of the animal food, i.e., to exogenous enzymes. The bile of the carp also contained proteases in an inactive form, which were activated by diluted intestinal liquor.

In extracts of animals which serve as food for the carp the greatest absolute proteolytic activity was shown by the extract of rainworms, *Eisenia* sp. *Tubifex* and *Daphnia* had considerably less absolute activity. Extracts of carp liver and pancreas were activated by the extract of *Tubifex* or *Daphnia*, carp bile by the extract of a mixture of Ostracoda and mosquito larvae (*Culex* sp.). It is suggested that in the intestinal mucosa of the carp and in the bodies of phylogenetically lower animals, e.g. (rainworm, *Tubifex*, Ostracoda and mosquito larvae) there is an enzyme activator, together with inhibitors which are probably products of enzyme activity. Only when the inhibitors become diluted is this enzyme effective in activating the proteases. (From author's summary.)—M. Prokšová (Czechoslovakia).

3532

SUNDARAM, T. K., RADHAKRISHNAMURTY, R., SHANMUGASUNDARAM, E. R. B. and SARMA, P. S. Tryptophan metabolism in rice moth larva (*Corcyra cephalonica* St.) *Proc. Soc. Exp. Biol. Med.*, 1953, **84**, 544-546. [Univ. Biochem. Lab., Guindy, Madras.]

See Abst. 2238, Vol. 24.

Paper chromatography was used to investigate the tryptophan metabolites in faeces extracts from larvae. The yellow pigment excreted by pyridoxine-deficient larvae receiving tryptophan consisted of kynurenine and 3-hydroxykynurenine. Both were absent when the larvae received pyridoxine. Several unidentified substances were present in extracts from faeces of both groups. The absence of xanthurenic acid was confirmed.

GHIRETTI, F. Enteramina, octopamina e tiramina nelle secrezioni esterna ed interna delle ghiandole salivari posteriori dei Cefalopodi Octopodi. [Enteramine, octopamine and tyramine in the external and internal secretions of the posterior salivary gland of octopod cephalopods.] *Arch. Sci. biol., Bologna*, 1953, **37**, 435-441. [Ist. Fisiol. Gen., Univ. Naples.]

Chromatographic analysis showed that when the posterior salivary glands of *Octopus vulgaris* were

N.A. and R., July 1954

electrically stimulated, tyramine, octopamine and enteramine passed into the perfusing liquid. Under the same conditions the glands of *Octopus macropus* secreted only tyramine and octopamine, so the high biological activity of perfusates of the glands of *O. vulgaris* is attributed to the enteramine.

Chromatograms of acetone extracts of the saliva of *O. vulgaris* revealed the presence of tyramine, octopamine, enteramine A and enteramine I. The enteramine I is probably a metabolic transformation product of enteramine A.

5. HUMAN DIET IN RELATION TO HEALTH AND DISEASE

DIET AND HEALTH

REQUIREMENTS

3537

ALLEN, T., MACLEOD, A. V. and YOUNG, E. G.
On the nutritional requirements of young children with particular reference to calcification. *Canad. J. Med. Sci.*, 1953, **31**, 447-461.
[Dept. Biochem., Dalhousie Univ., Halifax, N.S.]

Results are reported of a nutritional survey of 158 children aged from 1 to 6 years. One-week diet records were obtained by the weighing method, and bodyweight, height, chest circumference and pelvic girth were measured; Hb was estimated and counts of red and white cells were made in blood of 55 children; X-ray photographs were made of the bones of the wrist of 56 of the children. Repeat studies were made 6 months later.

As judged by current Canadian diet standards deficiencies of energy, Ca and vitamin D occurred most commonly. The standard of 1.0 g. daily for Ca was not reached by 78 per cent. of the children. Detailed analysis of the repeat data relating to 36 children showed that in half there was adequate calcification and growth on substandard diets and in 30 per cent. there was inadequate calcification and growth on substandard diets. It appeared that normal maturation of bone could take place on vitamin D intakes of 25 to 150 I.U. and of Ca of less than 1 g. daily.

Average Hb for all ages combined was 12.4 g. per 100 ml.—F. C. Aitken.

3538

NATIONAL RESEARCH COUNCIL, U.S.A., FOOD AND NUTRITION BOARD. **Recommended dietary allowances.** Publ. No. 302. Revised 1953, pp. 36.

The principal changes are the grouping of adults in 3 age, instead of 3 activity groups and in the method of expressing allowances of calories. The reference man and woman of the FAO Committee on Calorie Requirements and, in principle, the FAO adjustments for age, weight and environmental temperature are accepted. Some modifications and extensions of the scheme have been introduced. Calorie allowances are reduced by 5

instead of 7.5 per cent. per decade from 25 years of age, an increase of 0.5 per cent. per year from age 20 to 24 is allowed, account is to be taken in adults of "desirable" bodyweight, and for "extremely sedentary" subjects and invalids an allowance of 1.2 times basal metabolism is considered sufficient. The pregnancy allowance is 400 Cal. in the third trimester instead of 450 suggested by FAO and the lactation allowance is 1000 Cal. for 850 ml. milk (as suggested by FAO) or 130 [? 117] per 100 ml.

Children's allowances are modified only in respect of girls 10 to 12 years of age who are to have 2300 instead of 2500 Cal. because boys of this age are more active, and girls of 13 to 15 years who have 2500 instead of 2600.

Protein allowances for children are unchanged; those for adults are related to the new reference bodyweights.

Riboflavin allowances are derived by multiplication of the protein allowances by 2.5×10^{-5} . Allowances of Ca for adults are reduced to the pre-1948 level of 0.8 g. and for girls of 16 to 20 years increased to 1.3 g. Allowances are unchanged for Fe, ascorbic acid and vitamin D, and for vitamin A except for youths of 16 to 20 years who are to have 5000 instead of 6000 I.U. There are minor adjustments to relate vitamin B₁ to calories on a uniform basis and nicotinic acid allowances are ten times those of vitamin B₁.

Other nutrients are discussed in the text as before with the addition of vitamin B₆, vitamin B₁₂, pantothenic acid and biotin.—F. C. Aitken.

FEEDING OF INFANTS AND CHILDREN

3543

BARNES, G. R. (Jr.), LETHIN, A. N. (Jr.), JACKSON, E. B. and SHEA, N. **Management of breast feeding.** *J. Amer. Med. Assoc.*, 1953, **151**, 192-199. [Dept. Paediat., Sch. Med., Yale Univ., New Haven, Conn.]

The procedures used in the establishment of breast feeding and the management of problems in lactation are described.—F. C. Aitken.

3544

SÖDERLING, B. **Pseudoprematurity.** *Acta paediat.*, 1953, **42**, 520-525. [Dept. Paediat., Central Hosp., Borås, Sweden.] French, German and Spanish summaries.

It is indicated that the custom of defining prematurity in term of birthweight leads to neglect of the facts that premature infants of similar birthweight may differ in physiological maturity, and that they may therefore require different systems of management. Appetite is considered to vary with maturity and to be a better guide to feeding requirements than are quantities based on bodyweight. Rigid regimes of this kind may lead to overfeeding which may prove lethal, or to underfeeding and consequent low metabolism and low body temperature. Charts are given for the weight trends and energy intakes of 4 infants fed to appetite, and a plea is made for study of the phenomena of foetal maturity.—A. M. Thomson.

3545

BÜSCHER, L. and GLEISS, J. **Vergleichende Untersuchungen über die Ernährung der Frühgeburt mit Frauenmilch, Milchezucker-Eiweissmilch, Milchezucker-Fettmilch und Säure-2/3-Milch.** [Comparative investigation of human milk, lactose-and-protein milk, lactose-and-fat milk, and acid two-thirds milk for premature

infants.] *Monatsschr. Kinderheilk.*, 1953, **101**, 357-360. [Kinderklin., Med. Akad., Düsseldorf.]

Groups of 18 or 20 premature infants were given one of 4 types of milk from the second month of life, for from 4 to 6 weeks. The weight increase with lactose-and-fat milk and lactose-and-protein milk was intermediate between the highest increase with human milk and the lowest with acid two-thirds milk. With human milk metabolic disturbances and complications were much less frequent.—E. M. Hume.

3546

DELTHIL, P. **Essais d'alimentation complémentaire chez les prématurés.** [Trials of supplementary feeding of premature infants.] *Pédiatrie*, 1953, **8**, 917-924. [Centre Prématurés, Hôp. Saint-Denis, Paris.]

The special nutritional requirements of premature infants are discussed with particular reference to protein needs for rapid growth and vitamin and mineral supplements. A satisfactory supplementary feeding mixture was made up from aminoacids supplied by a yeast hydrolysate, with vitamin B₁, riboflavin, nicotinic acid, pantothenate, vitamin B₁₂, vitamin C, vitamin D, dicalcium phosphate, magnesium phosphate, manganese chloride and ferrous carbonate mixed with full cream dried milk. When suitable amounts of the mixture were given in addition to breast milk improved weight gains resulted. In the 42 premature infants which were given the mixture no sign of intolerance or digestive disturbance was recorded.

EWERBECK, H. **Die adaptierte künstliche Säuglingsnahrung, ein Eiweissproblem.** [Artificial humanised food for infants, a protein problem.] *Öst. Ztschr. Kinderheilk.*, 1953, **9**, 121-129. [Kinderklin., Univ. Cologne.]

Two commercial humanised milk preparations were studied. Though both approximated in their gross chemistry to human milk, electrophoretic analysis showed that the composition of their protein component approximated to that of cow's milk. Compared with breast milk the casein content was high and the whey protein was poor in β -lactoglobulin.—L. Wills.

- HATFIELD, M. A., SIMPSON, R. A. and JACKSON, R. L. **A study of the comparative response of young infants to human milk and to various types of cow's milk formulas.** *J. Pediat.*, 1954, 44, 32-45. [Dept. Paediat., Coll. Med., State Univ. Iowa.]

Evaporated milk preparations gave a higher incidence of irritation of the buttocks in newborn infants than did one with diluted cow's milk or breast feeding. There was no significant difference in stool pattern with difference in the method of artificial feeding. In this study there were 180 infants from birth to 6 days of age. In a study with 33 infants aged from 1 to 8 weeks, heat-sterilised evaporated milk preparations produced softer stools than did fresh milk or frozen evaporated milk preparations. Test periods in this study were each of one week's duration.

- REDDY, S. K., DORAISWAMY, T. R., SANKARAN, A. N., SWAMINATHAN, M. and SUBRAHMANYAN, V. **Effects on the general health and nutritional status of children of partial replacement of rice in a poor vegetarian diet by tapioca flour.** *Brit. J. Nutrition*, 1954, 8, 17-21. [Central Food Technol. Res. Inst., Mysore.]

Since previous experiments (Absts. 3293, 3520, Vol. 24) had indicated that 25 per cent. of the rice in a poor rice diet could be replaced by tapioca without ill effects on rats or adult men, a 6-month feeding experiment was made in an orphanage with 2 groups of about 30 healthy girls aged from 5 to 12 years. One group had the orphanage diet, of the usual South Indian type, mainly rice with small quantities of pulses and vegetables, and the other had 25 per cent. of the rice replaced by tapioca flour. A one-week dietary survey and calculation of the nutrient intakes showed that the rice-tapioca diet supplied slightly less protein and slightly more Fe than the rice diet; supplies of other nutrients were about the same, but nearly all were far below the Indian recommended allowances.

No difference was found between the groups in increments of height, weight or hip width, nutri-

Vol. 24, No. 3

tional status as judged by the recommendations of the Indian Council of Medical Research Nutrition Advisory Committee (1948), red cell count, or serum protein. Hb fell in both groups; the decrease was significantly less in the rice-tapioca group. It was concluded that the children's health had not suffered from the substitution of tapioca for 25 per cent. of the rice in their diet.

- BIANQUIS, CUVIER, LESNÉ and ROHMER. **Les modalités les plus convenables pour la distribution de lait à des enfants d'âge scolaire. [The best ways of distributing milk to children of school age.]** *Pédiatrie*, 1953, 8, 953-956.

The need of schoolchildren for extra milk is stressed. It was found unsatisfactory to give milk in the morning as it affected the appetite for the midday meal. At 4.0 or 4.30 p.m., however, milk was acceptable. It is suggested that it should be boiled and given warm and sweetened to increase its acceptability and energy value. Country children who may live far from the school have a special need for a milk supplement to their diets. Rickets and malnutrition are more common in rural children, and a further report is to be made on Ca requirements.

DIETARY SURVEYS AND INDIVIDUAL STUDIES

3554

- EIJKEL, R. N. M. **Wijze, waarop het onderzoek naar de voeding in gezinnen en gestichten kan worden uitgevoerd. [Diet survey methods for households and institutions.]** *Voeding*, 1954, 15, 56-67.

Families chosen for diet surveys should be representative of an area, both regionally and by occupation. For the whole country, about 1000 families should suffice; for a community or area with about 100,000 inhabitants, 80; for 20,000 to 100,000 inhabitants, 30 and for less than 20,000 inhabitants, 16 families. The statistician who will analyse the results should be consulted in advance. The choice of families should not select one class or type, but should be representative. Social organisations should help to procure volunteers.

The survey should be made by trained workers. The design of books for records is briefly discussed. The duration may be a week or a month at a time, and to give information for a year, there should be 3 surveys. The task is simpler in institutions than in private families.

The discussion of methods of analysis deals chiefly with man values or consumption units. There is a brief section on diet histories.

I. Leitch.

3555

YOUNG, C. M., CHALMERS, F. W., CHURCH, H. N., CLAYTON, M. M., MURPHY, G. C. and TUCKER, R. E. **Subjects' estimation of food intake and calculated nutritive value of the diet.** *J. Amer. Dietetic Assoc.*, 1953, **29**, 1216-1220. [Agric. Exp. Stat., Cornell Univ.]

Six groups of subjects, 25 and 16 children, 17 pregnant women, 56 male industrial workers, 14 and 21 college students, were asked to estimate the quantities of food which they ate at one or three meals. The quantities were measured and nutrient intakes were computed from estimated and measured food intakes.

For all the groups except one of the groups of children subjects' errors in estimating quantities of food had little influence on the accuracy of mean calculated intakes of nutrients. On an individual basis there were wide differences between nutrient intakes computed from estimated and measured food intakes.—F. C. Aitken.

3556

MINISTRY OF FOOD. **Domestic food consumption and expenditure, 1951. Annual report of the National Food Survey Committee.** H.M.S.O., London, 1953, pp. 116. Price 3s. 6d. net.

This report presents the data for 1951 and compares them with those for 1950 (see Abst. 764, Vol. 23).

Changes in the methods of collecting the data, which came into operation in June 1951 and are fully described in an appendix, were aimed at overcoming defects found in the system which was in use in 1950, and they resulted in a general simplification. For the 4 quarters of the year the mean amounts spent per head per week on food were 182.0, 193.7, 224.0 and 225.5 pence. The higher nutritive values for the latter half of the year reflected these changes. Value of consumption in 1951 was greater than in 1950 by 18 per cent., an increase similar to that of 16 per cent. which occurred in prices. In terms of food decreases in eggs, meat and to a less extent in fats and increases in fish, vegetables other than potatoes, fruit, sugar and preserves gave rise to small changes in 1951 compared with 1950 but, by the British Medical Association's standards, the levels of intake of energy and of 8 nutrients remained adequate.

In relating food consumption and expenditure to income and social status the system of classification was unchanged from the previous report. Class A included about 7 per cent. of both households and persons, Classes B and C, together, about 70 per cent. of households and 76 per cent. of persons; the remainder, Class D, were subdivided into old-age-pensioner households and others. Comparison was made with the previous

year by expressing value of consumption for each class as a percentage of the national average. At the end of 1950 differences between classes had widened, but by the end of 1951 these differences had narrowed. In nutritional value it appeared that energy value and Ca had declined slightly in Classes A and B; in Class D they had risen. Protein intake by Class D had also improved. In all classes intakes of Fe, vitamins A and B₁, riboflavin and nicotinic acid had increased.

When requirements were considered class differences were found to be small. Fe consumption, about which doubt regarding the standard may exist, was below the recommended amount in the old-age-pensioner households but except for some small shortages of energy the intakes for all classes were above the British Medical Association recommendations. When, however, the composition of the households was taken into consideration there was evidence that in the larger families, i.e., with 1 male and 1 female adult and 4 or more children, intakes of total protein and of Ca were low.

In the last half of the year expenditure on subsidised foods was a little over 9s. per head per week, nearly 50 per cent. of the total expenditure on food; the cash value of the subsidy was about 2s. 9d. per head per week or 30 per cent. of the expenditure on subsidised food.

The contributions of different foods to the nutrient content of the diet was examined; except for vitamins A, C and D, on which seasonal changes had their effects, there was great constancy of the proportions from particular foods.—D. Harvey.

3557

CHOMBART DE LAUWE, P., CHOMBART DE LAUWE, M. and BENOIT, O. *Étude sur certaines motivations du comportement alimentaire. 1. Ménages ouvriers (légumes, crudités, conserves).* [Some reasons for behaviour towards food. 1. Working-class households (vegetables, salads, tinned foods).] *Bull. Inst. nat. Hyg., Paris*, 1954, **9**, 119-132 (to be continued). [Centre d'Études Sociologiques, C.N.R.S., Paris.]

Food attitudes were investigated in 133 working-class households in Paris and its suburbs. Attitudes towards meat have already been reported (Title 772, Vol. 23). Potatoes and alimentary pastes are valued because they are "filling"; green vegetables, both cooked and raw, for their "refreshing" qualities, except by some who find they disturb digestion. Tomatoes, radishes and other non-green salad vegetables are regarded more as a luxury than a necessity. Fruits are valued, especially for children; men do not eat them much. Nearly half the people displayed ignorance of or contempt for vitamins. Tinned foods are

not much used except as an occasional convenience or luxury; apart from their cost, many dislike or distrust them. The same distrust of "artificial" foods was forcibly expressed by a variety of abusive remarks on margarine. Those who use it do so mainly for cooking and because of its cheapness.—W. M. Deans.

3558

DARBY, W. J., DENSEN, P. M., CANNON, R. O., BRIDGFORTH, E., MARTIN, M. P., KASER, M. M., PETERSON, C., CHRISTIE, A., FRYE, W. W., JUSTUS, K., MCCLELLAN, G. S., WILLIAMS, C., OGLE, P. J., HAHN, P. F., SHEPPARD, C. W., CAROTHERS, E. L. and NEWBILL, J. A. **The Vanderbilt cooperative study of maternal and infant nutrition. 1. Background. 2. Methods. 3. Description of the sample and data.**

DARBY, W. J., MCGANITY, W. J., MARTIN, M. P., BRIDGFORTH, E., DENSEN, P. M., KASER, M. M., OGLE, P. J., NEWBILL, J. A., STOCKELL, A., FERGUSON, M. E., TOUSTER, O., MCCLELLAN, G. S., WILLIAMS, C. and CANNON, R. O. **4. Dietary, laboratory and physical findings in 2,129 delivered pregnancies.** *J. Nutrition*, 1953, **51**, 539–563; 565–597. [Div. Nutrit., Dept. Biochem., Sch. Med., Vanderbilt Univ., Nashville, Tenn.]

1. This study concerned all pregnant white women who presented themselves for antenatal care at the Vanderbilt Hospital. Background data are presented from recalculations based on the work of Youmans *et al.* (Absts. 507 and 3360, Vol. 13) and Darby and Milam (Abst. 3575, Vol. 15) and from unpublished studies by Robinson, Steinkamp and Kaser.

2. At the time of the first visit each patient underwent a special nutritional and physical examination and blood was sampled for red cell count and packed cell volume measurement and estimations of serum ascorbic acid, carotene and vitamin A, total serum proteins and serum albumin. A week or so later tolerance tests with vitamin B₁, riboflavin and N¹-methylnicotinamide were made, after which the patients kept a 7-day record of food consumption from which average daily intakes of nutrients were calculated. Once during each subsequent trimester the diet studies, physical examinations and laboratory tests were repeated; 6 weeks *post partum* there were repetitions of the physical examinations and laboratory tests. The haematology and plasma protein levels of the infant were studied at 6 days of age and later generally in the second month.

3. From 1945 to 1949 pregnancies numbering 2338 and including two or more from 260 women were studied. The women belonged to "low to moderate" income groups. Information was com-

plete for only 2046 pregnancies but there was no reason to believe that the exclusion of 292 affected the representative nature of the population studied.

4. Mean energy and nutrient intakes are tabulated for each trimester. For energy the amounts were 2140, 2200 and 2020 Cal., 14 per cent. of which were derived from protein. Approximately 65 per cent. of the protein was of animal origin. Average Ca intake was about 1.4 g. daily. Although intakes of nutrients tended to be below accepted standards, the shortages did not cause concern. Woman who entered the study in a trimester later than the first recorded intakes of nutrients higher than those of women at the same stage of pregnancy who entered at an earlier trimester. It was not possible to decide whether these differences were due to appetite or whether they were the result of advice on weight restriction given by the physicians. Data are given for seasonal variations in energy intake and for the amounts of certain foods consumed in the third trimester. Other tables and diagrams summarise the laboratory findings. Women attending for the first time in the second and third trimesters had values generally higher than those attending earlier; the depressed haematological values may have produced an "ill-defined sense of less-than-buoyant health" in those who attended earlier. No clinically recognisable deficiency disease was seen, and in respect of subclinical signs there were variations from one examiner to another. The mean height of the patients was 64.0 in. and the mean weights were 122, 127, 139 and 126 lb. in the three trimesters and *post partum*, respectively.

A. M. Thomson.

3559

MURPHY, G. H. and WERTZ, A. W. **Diets of pregnant women: influence of socio-economic factors.** *J. Amer. Dietetic Assoc.*, 1954, **30**, 34–38. [Univ. Massachusetts, Amherst.]

Sixty-five women, private patient volunteers, kept records of food consumed for 7 days during early and late pregnancy and 3 months *post partum*. Quantities were recorded in terms of household measures. Average nutrient intakes are given and are compared with the recommended allowances of the U.S. National Research Council. Diets were classified into 3 groups according to the extent by which they fell short of the standards, and results were assessed in relation to the size of the family, weekly food cost per food expenditure unit, income, and social (occupational) class. Money spent on food was not related to income, or to adequacy of diet. As social levels rose, diets tended to improve.—A. M. Thomson.

3560

GOVIL, K. K., MITRA, D. and PANT, K. C. **Dietary habits of school boys in Uttar Pradesh.** *Indian*

Med. Gaz., 1953, **88**, 357-363. [Nutrit. Lab., Provincial Hyg. Inst., U.P., Lucknow.]

Foods consumed in 14 hostels were weighed for 1 week and mean daily intakes of nutrients per head were computed for each hostel. Compared with recommended allowances for Indian children diets were low in animal protein, Ca, vitamin A and ascorbic acid. Riboflavin intakes were borderline.

The results of this diet survey of 412 boys were in line with the findings in clinical studies of these and other children summarised here from a previous publication (Abst. 1049, Vol. 24).—F. C. Aitken.

3561

KARK, E. **The growth and nutritional state of Bantu girls in Durban.** *S. African J. Med. Sci.*, 1953, **18**, 109-124. [Inst. Family and Community Health, Durban.]

Girls numbering 365 and attending 2 schools in an African housing area in Durban were examined and, for 11 months, 300 were the subjects in a feeding experiment. Weight, height, sitting height, width, depth and circumference of chest and pelvic width were recorded.

Data are tabulated for mean weight and height for the age groups 8 to 15 years at yearly intervals and are compared with other South African findings for African and European children. The main abnormalities found by clinical examination are presented: dental caries in 56.2 per cent. and postural defects in 28.8 per cent. of the girls were by far the commonest disorders. Mean Hb for 211 girls was 11.78 g. per 100 ml. blood.

The extra food, given at school on 182 days, was $\frac{1}{2}$ pint milk or 8 oz. fruit syrup supplying the same energy, 200 Cal. The findings are discussed in respect of increases in weight and height, changes in appearance of skin and oral mucous membranes and absenteeism from school. Differences in growth of the girls between the groups were not significant. The skin was studied by noting occurrence in 9 areas of abnormalities of lustre, texture, pilosebaceous follicles and infections and other defects. Mucous membranes were also referred to regionally as lips, gums, buccal mucosa and tongue. In both groups there was improvement as measured by the increases in percentages of subjects found to have one or more skin regions normal and by the total number of normal skin regions within the groups. None had all 9 areas free from abnormality; the best had 4 areas which were normal. In respect of mucous membranes both groups were improved after extra feeding; the improvement in gums and tongue seemed to be greater in the milk than in the syrup group. Absenteeism, of which sickness was probably the main cause, was less, 2.76 per cent., in the milk than in the syrup group, 3.72 per cent.

It is concluded that in the girls' home diets

there may have been a shortage of energy which was made good by the extra feeding. Subsequent clinical findings after the end of the experiment are to be the subject of another report.—D. Harvey.

3562

JELLIFFE, D. B. and WILLIAMS, L. L. (with JELLIFFE, E. F. P.) **A clinical nutrition survey in a rural Jamaican village (with especial preference to the children).** *J. Trop. Med. Hyg.*, 1954, **57**, 27-40. [Univ. Coll. West Indies, Jamaica.]

In a hill village in Western Jamaica 252 persons, 87 per cent. of the population, who are of predominantly African descent, were clinically examined with special attention to hair, skin, mouth and eye changes which may point to malnutrition; the classification of these is described in detail. A qualitative account of the diet is given; it contains a wide variety of foods but very little animal protein. Children after weaning at about 12 months get only small amounts of sweetened condensed milk and few eggs, their main food being porridge of degermed yellow maize meal or other cereals.

Breast-fed infants appeared well nourished but children between 1 and 3 years were thin and anaemic, with palpable livers and dyspigmentation of the hair. Since malaria was absent and intestinal infestation uncommon, their state was ascribed to protein deficiency; but no case of manifest kwashiorkor was seen during the survey. Older children were thin but wiry and alert; hair changes were found in over a fifth of them, and mosaic skin, permanent gooseflesh and dyspigmentation of the face were common. Adults were on the whole of better physique; skin changes were much less common than among the children, and hair changes were not present. Slight angular stomatitis was not uncommon; cheilosis was rare, and no pellagrous rash, crazy pavement dermatosis or follicular keratosis was seen. Gingivitis and caries were prevalent among both children and adults. The former was ascribed to poor dental hygiene, not to lack of vitamin C, and the latter to the low Ca intake and the use of finely milled flour and sugar. The incidence of excess tissue of the bulbar conjunctiva and pterygia increased with age, but these were ascribed to exposure to sunlight, not to dietary deficiency.—W. M. Deans.

3563

VELEZ, F. and BRAUNSTEIN, A. B. **Encuesta de hábitos alimenticios en un grupo de escolares. [Study of food habits of a group of scholars.]** *Arch. venezol. Nutrición*, 1952, **3**, 419-431. [Inst. Nac. Nutrición, Caracas.] English and German summaries.

A study was made of the breakfast habits of 1064 children aged from 5 to 16 years; 86 per cent. were Venezuelan by birth and 75 per cent. were of the middle class.

The most popular foods and the percentages of children eating them were: sugar 71.2, coffee with milk 62.9, butter 61.9 and wheat bread 59.8. Arepa, a kind of maize biscuit, and cheese were eaten by 41.0 and 40.0 per cent. of the children, respectively. Milk was taken by 27.5 per cent., eggs by 17.5, citrus fruits by 5.3 and fruit juice by 4.7 per cent. Four children, 0.4 per cent., had no breakfast.

One or 2 foods only were eaten by 7.3 per cent., 3 to 6 foods by 87.0 per cent. and 7 to 11 foods by 5.7 per cent. of the children.

Heights and weights were compared with the official national standards and, on this criterion alone, 86.6 per cent. of the children were considered to be adequately fed and 13.4 per cent. to be undernourished, but most of them only slightly so.—P. C. Jowsey.

3564

BENGOA, J. M., OBREGON, V. M. and GONZALEZ, M. Influencia del factor economico en el consumo de alimentos en el medio rural. [Effect of economic circumstances on food consumption in a rural area.] *Arch. venezol. Nutricion*, 1952, 3, 343-418. English and German summaries.

See Abst. 3394, Vol. 23, for a general survey of the district.

The data obtained from a week's dietary survey in Santa Teresa del Tuy of 152 families with a total of 789 persons, representing 18 per cent. of the population, are set out in 54 tables and 24 graphs. The families were divided into 5 groups according to income.

In Group 1, 44 families, the monthly income was below 200 bolivars (B.), and the average daily expenditure on food per person was B. 1.06. In this group there were grave nutritional deficiencies, calling for assistance beyond educative work. The average intakes per person were: energy 1282 Cal., protein 46.8 g., of which only 8.8 was of animal origin, Ca 0.27 g., vitamin A 626 I.U., riboflavin 0.45, nicotinic acid 2.8, vitamin B₁ 0.68, and vitamin C 18 mg. The Fe intake of 13.5 mg. was higher than the allowance recommended by the U.S. National Research Council. The basic foods of the group were cereals, unrefined sugar and black beans. Consumption of fish and meat was 28 g. per head, of milk 43 ml. and of powdered milk 7 g. Practically no eggs, butter, root vegetables, tubers, green vegetables or fruit were consumed.

In Group 2, 46 families with monthly income between 201 and 400 B., the average daily cost of

food per person was B. 1.23. This group showed an increase in quantity rather than in quality of the foods consumed and had significantly more Calories (1657) and protein (55.9 g.) per person than Group 1; there was practically no change in the amounts of Ca, Fe, vitamin B₁, riboflavin, nicotinic acid and vitamin C.

In Group 3, 29 families with monthly incomes between B. 401 and 600, the daily expenditure on food per person was B. 1.50. The food in this group was better than that of the two preceding groups. Consumption of energy, protein, Fe, vitamin B₁ and nicotinic acid was satisfactory, but that of Ca, vitamin A, riboflavin and vitamin C was only about 50 per cent. of the requirement. In this group educative work might well effect improvement in the diet.

In Group 4, 16 families having incomes from 601 to 800 B., and a daily expenditure on food of 1.81 B., the characteristics were similar to those of the third group, except for an increase in protein consumption, especially of animal protein.

In Group 5, comprising 14 families with incomes of B. 801 or more and a daily food expenditure of 2.21 B., food conditions were satisfactory, except that the intakes of Ca and vitamin A were still inadequate.

Economic conditions greatly influenced the consumption of wheat bread, meats, milk, eggs and fresh vegetables, and only to a slight extent the consumption of maize, rice, other cereals, oatmeal, lard, legumes and unrefined sugar. For all the families studied the nutritive values per person per day were: energy 1670 Cal., protein 55.9 g., Ca 0.43 g., Fe 12.6 mg., vitamin A 1082 I.U., vitamin B₁ 0.73, riboflavin 0.68, nicotinic acid 6.7, and vitamin C 36.7 mg.—M. B. Richards.

3565

ARESCURENAGA C., H. Contribución al estudio de la alimentación del indígena peruano. [Contribution to the study of the diet of the Peruvian native.] *An. Fac. Farm. Bioquim.*, Lima, 1952, 3, 116-121.

A diet study was made at the village of Sañus, 7 km. from the city of Huancayo.

Daily intakes per head of nutrients varied between the following limits: energy 755.0 to 1175.5 Cal., protein 6.9 to 23.9 g., fat 7.3 to 14.7 g., carbohydrates 151.2 to 248.0 g., P 66.7 to 137.5 mg. Intakes of Ca, Fe and vitamins were generally insufficient. The diet contained a high proportion of cellulose.

Among the recommendations made were that the natives should be educated in what foods are necessary, that they should be urged to grow them wherever possible, and that the cultivation of "tumbo" should be encouraged. This fruit belongs to the passion-fruit family, contains 92.3 mg.

vitamin C and 38.7 mg. P per 100 g., and grows well in the region investigated.—P. C. Jowsey.

UPJOHN, H. L., SHEA, J. A., STARE, F. J. and LITTLE, L. **Nutrition of athletes.** *J. Amer. Med. Assoc.*, 1953, **151**, 818-819. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

The principles of nutrition of athletes are the same as those of nutrition of non-athletes. A nutritionally adequate diet in amounts sufficient for energy requirement and maintenance of desired bodyweight should be the rule. The timing of meals should be related to the times of exercise to allow of efficient digestion and efficient athletic performance.—F. C. Aitken.

3585

SURE, B. **A low-cost, high protein, low calorie food.** *J. Clin. Nutrit.*, 1953, **1**, 534-538. [Dept. Agric. Chem., Univ. Arkansas, Fayetteville.] Spanish summary.

The food is based on defatted soya flour, with dried non-fat milk solids, roughly ground whole wheat, vegetable shortening and tomato ketchup, and added vitamin B₁, riboflavin and nicotinic acid. It contains protein 17, fat 2.7, ash 3.0, Ca 0.3 and water about 60 per cent.; vitamin B₁ 8.1, riboflavin 7.1, nicotinic acid 31.1, pantothenic acid 8.2 and vitamin B₁₂ 0.1 µg. per g. Its protein value is claimed to be equal to that of beef and 92 per cent. of that of dried whole egg, but the energy value is only 750 Cal. per lb. It is said to have a nutty meaty flavour and a meaty texture and to have proved widely acceptable as a supplement or substitute for meat; some representative recipes are given. Commercial production is envisaged at an estimated cost of about 20 cents. per lb. can and 14 to 15 cents per lb. in 10-lb. cans for institutional use. It should be of use also for overweight persons.—W. M. Deans.

FOOD ECONOMICS AND STATISTICS

3593

- HEALEY, D. T. **The problem of population growth.**
 NILSON, S. S. **Replies to Mr. Clark's article.**
Internat. Labour Rev., 1954, **69**, 68-73;
 73-76. [Dept. Appl. Econ., Univ. Cambridge;
 Central Bur. Statistics, Norway.]

The first of these replies is entitled "The problem of population growth". It rejects all or most of Clark's premises and arguments on potential production (Abst. 1044, Vol. 24) and appears to deduce opposition to family limitation: "we cannot stand aside and watch while the fruits of scientific efforts are nullified by the appearance of ever increasing numbers of mouths".

The second reply implies that Clark has underestimated the danger of growth of population. It discusses, on the basis of reports to the First All-

Indian Conference on Family Planning (Bombay, 1951), the acceptibility of family limitation by Far East, especially Indian, peoples.—I. Leitch.

DIET IN ETIOLOGY OF DISEASE

GENERAL STUDIES

3595

- GORDON, H. H., LUBCHENCO, L. and HIX, I. **Observations on the etiology of retrolental fibroplasia.** *Bull. Johns Hopkins Hosp.*, 1954, **94**, 34-44. [Dept. Paediat., Univ. Colorado, Denver.]

Information on the status of the eyes up to at least 3 months of age were available for 211 premature infants of birthweight less than 1.5 kg. who had been given oxygen in the premature infant centre. Data for 20 infants were obtained during about 3 years when the design of incubators and method of supplying oxygen probably gave moderate concentrations of oxygen (group 1). During the next 5 months more efficient incubators and a piped oxygen supply gave concentrations of 60 per cent. and over as shown by scattered analyses. Data for 20 infants cared for during this time are presented (group 2). There followed a transitional period of 3 months in which lower concentrations of oxygen were gradually introduced, when 14 infants were studied (group 3). Finally, during 2 years oxygen concentrations were restricted to 30 to 40 per cent. for 97 infants (group 4).

The incidence of residual lesions of retrolental fibroplasia and retrolental membranes, respectively, was 15 and 10 per cent. in group 1; 45 and 35 per cent. in group 2; 29 and 21 in group 3; 8 and 2 per cent. in group 4.

The results indicate that retrolental fibroplasia is a disease in the etiology of which high environmental oxygen is most important, but it is recognised that condition of the capillaries at birth, rate

of growth and dietary components such as electrolytes and tocopherol may play some part in the etiology of the disease.—F. C. Aitken.

3596

- COXON, M. W. **Experiences with retrolental fibroplasia in Oxford.** *Proc. Roy. Soc. Med.*, 1953, **45**, 863-865.

Since Owens and Owens (*Amer. J. Ophthalmol.*, 1949, **32**, 1631) claimed good results for vitamin E in prevention or arrest of retrolental fibroplasia, all premature babies born in the United Oxford Hospitals between April 1950 and May 1951 were treated from 1 week to 6 months of age with 150 mg. α -tocopherol acetate daily. Five developed retrolental fibroplasia and there was no evidence of any lessening of its severity.

Attention was later directed to the role of oxygen and this is now limited to the minimum necessary to prevent cyanosis, with an oxygen concentration not exceeding 40 per cent. and reduced gradually. If retrolental fibroplasia develops, adrenocorticotrophic hormone is given; vision was saved in the 11 cases treated so far.

3598

POLUNIN, I. **The medical natural history of Malayan Aborigines.** *Med. J. Malaya*, 1953, 8, 55-114; 114a-174. [Dept. Soc. Med., Univ. Malaya.]

Census data are not complete for Malayan aborigines. In 1947, 35,000 were counted, but this may be an underestimate; there may be as many as 100,000. There are 3 main divisions, aboriginal Malays in South, Senoi in Central and Negritos in North Malaya. Three grades of economy are distinguishable, the simplest where a living is obtained by hunting, fishing and digging wild roots, the second and most widespread a system of shifting agriculture, and the third and most advanced with plantations of rubber and fruit trees.

Four groups were studied intensively in different areas, a method of study considered better than that of random sampling. They were (1) 171 Semai, the main southern group of Senoi, who had lived between 350 and 600 ft. above sea level, and (2) 178 Semai who had come from an altitude between 2750 and 4000 ft. Because of the internal troubles in the country these groups had, at the time of the survey, been evacuated to a lower altitude. Until their clearings came into bearing they were given a daily ration of rice, sweet potatoes, dried sprats, chillies and salt which provided 1300 Cal. per head. Group 3 was of 164 Negritos in Upper Perak whose shifting agriculture was haphazard, group 4 comprised 149 Orang Seletar; a people with a maritime or riparian mode of life in the south of Johore.

Vital statistics on the age of the subjects were unobtainable; there appeared to be a preponderance of young people, and of the 513 in the first 3 groups only 24 men and 19 women were classified as over 60 years of age. The excess of males over females was constant among nomadic aborigines. Child mortality was high. Heights were obtained for 297 adults over 20 years of age; the mean values in cm. and, in brackets, the numbers of those measured in the respective groups were, for men: 154.7 (50), 158.0 (35), 154.4 (41) and 162.9 (23) and, for women: 144.3 (44), 147.8 (43), 144.0 (42) and 150.4 (19). Data for weights are not considered representative because of the losses caused by the movement of the population during resettlement.

The information collected was primarily medical in nature and full details of the findings are presented. Disease of nutritional origin was not frequent. Among the Semai loss of weight as estimated from clinical examination was considerable in those from both altitudes but signs of deficiency of vitamin A, B vitamins, or vitamin D were not seen and on only few occasions were skin changes suggestive of dietary deficiency noted.

Angular stomatitis was seen in about 10 per cent. of the Semai but not in others. Thyroid enlargement, apparently from iodine deficiency, occurred in about 40 per cent. of the aborigines and neighbouring Malays. Enlargement of the parotid was common, palpable in 69 and visible in 33 per cent. of the population studied; incidence ranged from 85.8 to 56.4 per cent. Its possible relation to malnutrition and causation by work hypertrophy of the secretory cells are discussed.

Blood pressure, measured in a few Semai, was found to be low and to fall slightly with ageing. Hb was estimated by the modified cyanmethaemoglobin method of Cheek (*Trans. Roy. Soc. Trop. Med. Hyg.*, 1950, 44, 352) and Semai who had lived at the lower altitude where malaria, yaws and chronic pulmonary disease were common did not have lower Hb values than did Semai for the higher altitude who were relatively free from these illnesses.

The migration and resettlement of aborigines made necessary by the emergency have increased the death rate among those affected but epidemics have not occurred. The pattern of incidence of disease appears not to have changed but inadequate feeding may have played a part in reducing resistance among adults to diseases such as malaria, measles and dysentery and in increasing the hazards for infants by limiting lactation in the mothers.—D. Harvey.

3599

BLANCO OTERO, M., TARACENA DEL PIÑAL, B. and GARRIDO LESTACHE, J. Alimentación del niño español en relación con su crecimiento. [**Diet of the Spanish child in relation to growth.**] *Rev. española Pediat.*, 1953, 9, 951-965. [Sec. Fem. F.E.T. and J.O.N.S., Madrid.] French, English and German summaries.

A study of 8000 children between the ages of 3 months and 5 years, from all the Spanish provinces, showed a 10 per cent. retardation in the weight curve compared with what is regarded as normal. The retardation increased from about 9 months to a maximum in the second year. Estimation of food intake for the 24 hr. preceding the time of the body measurements showed deficits in the intakes of energy, protein and fats of 1/15, 1/10 and 1/7, respectively, of normal requirements, the deficit in energy being parallel to the deficit in bodyweight. The energy deficit from lack of fat and protein was made good in part by carbohydrates. These deficits gave rise in the more advanced stages to a clinical picture of grave malnutrition; when the signs were less marked, the condition might be wrongly diagnosed, in routine clinical work, as rickets.

M. B. Richards.

3600

WALLIS, A. D. **Dietary eggs and rheumatic fever.** WALLIS, A. D. and VIERGIVER, E. **Serum phospholipid and rheumatic fever.** *Amer. J. Med. Sci.*, 1954, **227**, 167-170; 171-178. [Ayer Clin. Lab., Pennsylvania Hosp., Philadelphia.]

The blood serum contains a substance which inhibits streptolysin S, one of 2 haemolysins produced by the group A beta haemolytic streptococcus which is believed to cause rheumatic fever. Since the activity of this inhibitor depends partly on the serum phospholipin content (see Wallis and Viergiver, *Amer. J. Med. Sci.*, 1954, **227**, 431), and this in turn on dietary choline, about half of which comes from eggs, 184 white and coloured patients, mainly adults and adolescents, and 1380 normal persons, were questioned about their present and past liking for and use of eggs. Ten per cent. of the cardiac patients, but just under 5 per cent. of the normal persons, expressed a present dislike of eggs. In both categories more females than males disliked eggs. Forty per cent. of the cardiac patients, but only 16 per cent. of the normal persons, said they had few eggs (4 or fewer weekly) in childhood, owing to dislike or poverty. Among patients with heart disease severe enough to require digitalis and those with 3 or more acute attacks of rheumatic fever, about 50 per cent. ate few eggs in childhood. It is suggested that individual differences not only in choline intake but also in choline requirement may affect susceptibility to rheumatic fever.

Lipoid P was estimated in the serum of 178 of the same patients, in all of whom the disease was inactive, and in a comparable number of normal persons. The results are shown graphically. For normal children and for normal adults between 20 and 39 years the respective mean values were 8.2 and 9.7 mg. per 100 ml. About 2/3 of the cardiac patients had values below average, but this difference was not found after age 35. Eighty per cent. of the cardiac patients had either a low serum phospholipin value or a low intake of eggs in childhood or both, and the percentage was even higher among those who required digitalis or who had had repeated attacks of rheumatic fever.

W. M. Deans.

3601

FRADÁ, G. and MENTESANA, G. Su alcuni rilievi nella fluorosi cronica. [**Observations on chronic fluorosis.**] *Boll. Soc. ital. Biol. sper.*, 1953, **29**, 750-753. [Ist. Patol., Univ. Palermo.]

Fluorosis caused by a high content of F in the drinking water is common in Sicily. Thirty-one men and women, fishermen and peasants, were examined. Dental fluorosis was severe, and there were complaints of dyspepsia and of pains in the joints, particularly of the legs. The red cell count

was low. X-ray examination showed skeletal changes and signs of gastroduodenal catarrh. In the blood serum alkaline phosphatase was somewhat high, inorganic P was usually normal, and total cholesterol was often low.—E. M. Hume.

3602

WADHWANI, T. K. **Prevention and mitigation of fluorosis (endemic).** 2. *J. Indian Inst. Sci.* [4], 1954, **36**, 64-69. [Sect. Pharmacol., Indian Inst. Sci., Bangalore 3.]

Earlier work on monkeys has been reported in Abst. 2504, Vol. 22.

A village was chosen in a district where fluorosis is endemic among humans and cattle and X-ray pictures were made of skeletons of 9 patients who were otherwise healthy but who had signs of fluorosis. For 6 weeks each was given 100 mg. vitamin C daily, after which additional X-ray examinations were made. These provided evidence of decrease in the size of the exostoses, and all patients reported less pain, a reduction in tingling sensations and improved movement of limbs. During the first 3 weeks of treatment all experienced more generalised pain.—D. Harvey.

VINAŘICKÝ, R. . Pokus o zlepšení výkonnosti v běhu na střední vzdálenost vitaminy B₁, B₂ a C. [**An attempt to improve the efficiency of medium-distance runners by large doses of vitamins B₁, B₂ and C.**] *Scripta med.*, 1954, **27**, 1-18. [Physiol. Inst., Med. Fac., Masaryk Univ., Brno.] English and Russian summaries.

The effect of prolonged daily administration of vitamin B₁ 7 mg., riboflavin 5 mg. and vitamin C 300 mg. on the efficiency of runners in 800-metre races was investigated. The runners were identical twins with identical training and programmes, living conditions and sports records. Their food was planned and its vitamin content was in accordance with generally accepted requirements.

N.A. and R., July 1954

During the experiment one of the twins took the additional vitamins in wafer capsules and the other took lactose and citric acid in similar capsules, neither knowing which was which. After several months the treatments were reversed. Such administration of vitamin B₁, riboflavin and vitamin C above the normal intake in food had no effect on efficiency as medium-distance runners, and it is concluded that allowances which suffice for hard work are sufficient also for athletes in hard training.—M. Prokšová (Czechoslovakia).

MARÍA BENGÓA, J., VÉLEZ BOZA, F. and DE SHELLY HERNÁNDEZ, R. La mortalidad por enfermedades carenciales en Venezuela en el decenio 1940-1949. [Deaths from deficiency disease in Venezuela in the decennium 1940-1949.] *Arch. venezol. Nutricion*, 1953, 4, 85-112. [Inst. Nac. Nutric.] English and German summaries.

A study in Venezuela of the number of deaths due to deficiency diseases for the period 1940-1949 showed an average of 10 yearly per 100,000 inhabitants. Of these deaths 53 per cent. were of children from 1 to 4 years of age; in this age group 36 of every 1000 deaths recorded were due to deficiency diseases. Of these children 61 per cent. showed the syndrome of multiple deficiency known as kwashiorkor. The importance in the national campaign against malnutrition of directing special attention to the children of pre-school age is stressed.—M. B. Richards.

3607

BURGIO, G. R. and GIACALONE, O. Reperti elettroforetici nella distrofia del lattante. [Electrophoretic findings in infantile dystrophy.] *Boll. Soc. ital. Biol. sper.*, 1953, 29, 695-698. [Clin. Pediat., Univ. Palermo.]

A syndrome of multiple deficiency, common in Sicily, affects children of 2 years old or less. The signs include some of those of riboflavin deficiency, oedema and changes in the blood and liver. Electrophoretic analysis of the blood serum of 10 children with the syndrome and of 5 normal children showed increase of α -globulin and decrease of γ -globulin, the latter being directly related to the severity of the dystrophy. There was a decrease in the percentage of albumin which was well marked in 2 children only.—E. M. Hume.

3608

OOMEN, H. A. P. C. Preliminary survey on malignant malnutrition in Djakarta toddlers. *Doc. med. geogr.*, 1953, 5, 193-214. [Inst. Nutrit., Djakarta, Indonesia.]

The patients were selected as clear cases of malnutrition from out-patients attending the Central

Hospital, and represented a cross-section of the less prosperous urban population. It was obvious from the numbers seen, 146 in 2 months, that malnutrition was a serious problem in this population. In 100 consecutive cases studied, the usual signs of malignant malnutrition were present, the most striking and most frequent being retardation of growth, liver enlargement, emaciation, depigmentation of hair, and muscular atrophy; oedema was present in only 35 per cent. Other lesions not commonly seen in malignant malnutrition were xerophthalmia and keratomalacia, which were present in 71 and 47 per cent. of the cases, respectively. Liver biopsy on 46 patients showed moderate or severe steatosis in 40, slight fibrosis in 27, and slight cellular infiltration in 27. The mortality rate was high. The eye lesions were evidence of vitamin A deficiency, but xerophthalmia alone, without signs of general malnutrition, was rare. A dietary investigation showed that most of the children were breast fed for the first year and were then weaned on to a rice diet often low in energy and deficient in protein. Dysentery, tuberculosis and other infections were frequently present, and apparently played an important part in the etiology. In many instances the faulty diet was due to ignorance rather than to poverty. A high-protein diet cured many patients.

L. Wills.

3609

DEAN, R. F. A. Treatment and prevention of kwashiorkor. *Bull. World Health Organiz.*, 1953, 9, 767-783. [Med. Res. Counc. Group Res. Infantile Malnutrit., Kampala, Uganda.] French summary.

In this expansion of a communication to the Conference of the *Centre International de l'Enfance* held at Brazzaville in 1952 the work in progress at Kampala is summarised. Treatment first with milk concentrates and later with soya beans as sources of protein was tried and the preparation of a soya-banana diet which has been found to be satisfactory is described in detail.

The economic implications of a number of different ways in which protein might be made available in larger amounts for the population of the East African territories are considered, and the view is expressed that, while animal sources should continue to be developed, they are unlikely to be able to supply the needs fully. Plant proteins have provided promising results and further investigation, especially of a combination of sunflower seeds and soya beans, is recommended.—D. Harvey.

LULLA, B. N. **Nutritional oedema in Sindhi evacuees. A clinical study.** *Antiseptic*, 1953, **50**, 789-793. [Pravin Court, Queen's Rd., Bombay.]

Diet histories, clinical features and laboratory findings in 12 cases are described. Diets were low in protein, vitamins and Fe. Anaemia was commonly associated with the oedema. Low blood plasma protein was the most significant laboratory finding, and the oedema was attributed to chronic protein deficiency.—F. C. Aitken.

3613

MEYERINGH, H. **Über Spätfolgen der Dystrophie. [Late effects of dystrophy.]** *Deutsch. med. Wochenschr.*, 1954, **79**, 241-242. [Landesversorgungsamts, Schleswig-Holstein.]

Report of a lecture. Among 56,000 former prisoners of war in Schleswig-Holstein, of whom many had had 3 or 4 years' captivity and all were more or less dystrophic, 8 have been found with organic brain disease due to dystrophy. The incidence of liver damage and disturbances of the nervous system, but not of organic heart disease, is higher than in the general population; fewer of the ex-prisoners show raised blood pressure.

Vitamin A

3614

PESKIN, J. C. **Effects of vitamin A on visual threshold.** *J. Appl. Physiol.*, 1953, **6**, 375-378. [Dept. Biol., Univ. Rochester, N.Y.]

Subjects whose dietary conditions had been nearly identical for several months before their selection and whose visual threshold, measured with the adaptometer of Hecht and Schlaer, was below 3.60 (log I $\mu\mu$ lamberts) were divided into two groups. The first group of 20 was left untreated and the second of 40 was given 50,000 I.U. vitamin A as a concentrate, daily for 35 days during which the threshold of each subject was tested every 4 to 6 days. The average threshold of those untreated remained constant. Of the 40 subjects receiving vitamin A, the average threshold of 34 fell by less than 0.07; that of the other

6 showed a steady decline from an initial value of 3.35 to a final one of 2.72 after 35 days.

LAHIRI, K. D. and SCANDRETT, F. J. **High vitamin A levels in the blood serum in certain skin diseases.** *Indian Med. Gaz.*, 1953, **88**, 639-641. [Dept. Dermatol., Royal Infirmary, Edinburgh.]

Carotene and vitamin A were estimated in the blood serum of patients in the Dermatological Department of the Royal Infirmary, Edinburgh, and the results were compared with values obtained for normal healthy subjects. Patients with psoriasis showed consistently high vitamin A values, the average in I.U. per 100 ml. for 17 being 223 compared with 187 for 114 normal controls. Values for carotene in I.U. per 100 ml. averaged 57.5, and were near to the average of 69 for the normal controls. Patients with other skin diseases also had high vitamin A values. The average for 15 patients with *lichen planus* was 252, for 6 with *lupus erythematosus* 210, and for 2 with *keratoderma palmaris et plantaris* 212. The last named patients had been given 100,000 I.U. vitamin A daily by mouth for 3 months. The respective average values for carotene were 81.2, 38.7 and 65.0, and were not, therefore, substantially different from those of normal controls. These preliminary results did not allow any definite conclusion to be drawn about abnormalities of vitamin A metabolism in these skin diseases, but it is suggested that there may be failure of normal utilisation.

Vitamin E

3617

GORIA, A. **Rirespirazione di miscele a bassa concentrazione di O₂. [Re-respiration of mixtures with a low concentration of oxygen.]** Effetti, nell'uomo, dell'alfatocoferolo sulla frequenza cardiaca. [Effect of α -tocopherol on the heart frequency in man.] Effetti del tocoferolo sui caratteri dell'elettrocardiogramma dell'individuo normale a riposo. [Effects of tocopherol on the electrocardiogram of normal subjects in repose.]

GORIA, A. and MALLIN, J. **Effetti dell'alfatocoferolo sull'elettrocardiogramma. [Effects of tocopherol on the electrocardiogram.]** *Boll. Soc. ital. Biol. sper.*, 1953, **29**, 1275-1276; 1277-1278; 1278-1279. [Ist. Fisiol., Univ. Turin.]

Two young adults took orally 100 mg. DL- α -tocopheryl acetate daily for 10 days and then 300 mg. daily for 10 days. On the 20th day, while at rest, they breathed for 3 min. a concentration of O₂ as low as could be tolerated, to the point of losing consciousness. The experiments were repeated 2 months later without previous administration of tocopherol. The progressive increase of pulse rate during the 3 min. test was less when tocopherol had been taken.

In the same circumstances, the electrocardiogram recorded prolongation of both systole and diastole when vitamin E had been given; the effect on diastole was the greater.

The other changes in the electrocardiogram promoted by a low O₂ concentration were to some extent favourably modified when vitamin E had been given.—E. M. Hume.

3618

GOUNELLE, H., MARNAY, C. and BLONDIN, M. Les troubles d'absorption de la vitamine E chez les sujets gastrectomisés. [**Disturbances of vitamin E absorption in gastrectomised subjects.**] *C.R. Soc. Biol.*, 1953, **147**, 1598–1599. [Centre Recherches Foch, Paris.]

The absorption of vitamin E was studied in 9 gastrectomised subjects. The vitamin was estimated in the serum of each patient, fasting and 6 hr. after taking 2 g. free α -tocopherol. Seven of the patients had been gastrectomised between 3 weeks and 2 months previously. The remaining 2 were gastrectomised 3 and 4 years earlier. The average percentage rise in the recently gastrectomised patients was 41 per cent., which is much less than the value of 118 previously reported (Abst. 2324, Vol. 24) for normal subjects. Faulty absorption of the vitamin was also shown in the long-standing gastrectomised subjects, the percentage rises for these being 24 and 70 per cent.

I. M. Sharman.

3619

SUTTON, D. C., SUTTON, G. C., HINKINS, G. F., BUCKINGHAM, W. B. and RONDINELLI, R. **Studies on whole blood and muscle creatine levels: effect of systemic and local anoxia, of cardiac failure and compensation, and of alpha-tocopherol administration.** *Amer. Heart J.*, 1954, **47**, 67–76. [Preble Res. Lab., Cook County Hosp., Ill.]

In 40 healthy subjects, mostly male, the whole blood contained from 1.0 to 2.6, mean 1.6, mg. per cent. creatine, estimated chemically. In 118 patients, cases of anaemia, anoxia, azotaemia and cardiac failure being excluded, values of from 1.6 to 2.9, mean 2.2 were found, but the difference between the healthy and the sick group was not statistically significant. Muscle obtained by biopsy

from 5 male patients with different diseases contained from 235 to 365 mg. per cent. In 16 subjects in which blood was first taken from the right arm, and next from the left arm after constriction for 20 min., increases of from 0.9 to 6.7, mean 2.4, mg. were found. In 17 patients with cyanosis or anaemia the blood values were from 3.1 to 4.9, mean 3.9, and in 150 patients with cardiac failure from 3.0 to 10.7, mean 5.2. In 25 cardiac patients serial estimations were made, and high values were gradually attained in 4 fatal cases. In 10 patients in whom compensation was effected by treatment with digitalis, barbitol and diuretics the average creatine content of the muscles rose from 256 to 330 mg. per cent. and that of the blood fell from 6.2 to 3.4 mg. per cent. When daily doses of 50 mg. α -tocopherol were given in addition to the other drugs, the increase of creatine in the muscle was somewhat greater, from 245 to 412, and again there was a fall from 6.2 to 3.4 in the blood values.

T. Moore.

3620

NUÑEZ MELGAR Z., Y. Variaciones de la creatinuria por influjo del alfa-tocoferol. [**Changes in excretion of creatine under the influence of α -tocopherol.**] *An. Fac. Farm. Bioquim., Lima*, 1952, **3**, 325–340. [Hosp. 2 de Mayo, Lima.]

Creatine and creatinine were estimated by photolorimetric methods in the urine of patients with cardiac or muscular disturbances or signs of senility. In muscular disturbances excretion of creatine was high and fell when α -tocopherol was given orally or by injection. Doses of from 20 to 60 mg. were used and the greatest effect was obtained with oral administration.

In senile patients and those with cardiac lesions the amount of creatine in the urine rose with increasing doses of tocopherol. The results of studies on 28 patients are set out in tables and graphs.—A. M. Copping.

WILSON, M. G. and PARRY, E. W. **Clinical trial of alpha-tocopherol in the prophylaxis of thrombo-embolism.** *Lancet*, 1954, **266**, 486–488. [Royal Infirmary, Bristol.]

Daily doses of 200 mg. α -tocopheryl acetate and intravenous injections of 10 ml. of 10 per cent. calcium gluconate every 48 hr. were given to 100 surgical patients, over 40 years old, of both sexes; 100 untreated patients acted as controls. In the treated patients mild deep thrombosis occurred in 7, and mild superficial thrombosis developed in 3. In the untreated patients non-fatal pulmonary embolism occurred in 2, severe thrombosis in 9, mild deep thrombosis in 3, and severe superficial

thrombosis in 1. The tocopherol therefore appeared to have some value in preventing thrombosis. Subsequently 3 groups of patients were left untreated, or were treated with α -tocopheryl acetate, calcium gluconate and vitamin D by mouth, or with α -tocopheryl acetate only. The incidence of cases of thrombosis in the 3 groups was 7, 5 and 2, respectively.—T. Moore.

Vitamin B Complex

3624

WILLIAMS, R. R. **The world beriberi problem today.** *J. Clin. Nutrit.*, 1953, **1**, 513-516. [Williams-Waterman Fund for Combat of Dietary Dis., Res. Corp., 405 Lexington Av., New York.]

In Japan the death rate from beriberi was 44 per 100,000 in 1923 but was falling gradually before the last war, when a further fall to 6 per 100,000 occurred as the result of restricting to 5 per cent. the amount of bran removed from rice. In the Philippines better medical attention in the towns has reduced the death rate. For other Asian countries statistics are less complete and there are still regions, especially in areas of industrial development, where beriberi is endemic. It is suggested that the sale of white rice should be prohibited. In Bataan a large-scale experiment showed that consumption of fortified rice reduced the beriberi mortality to a negligible level. Control of the milling and parboiling processes would have the same effect and would be more consistent with the type of economy prevalent in Asia.

CHHUTTANI, P. N. and TAYLOR, G. F. **Nutritional peripheral neuropathy related to "the shoulder girdle syndrome" in Persia and Iraq force 1944-45.** 1. 2. *Indian Med. Gaz.*, 1953, **88**, 509-520; 563-570. [Dept. Clin. Med., Med. Coll., Amritsar.]

1. Observations are reported on 83 cases of which 13 are described in detail.

2. Differential diagnosis from other peripheral nerve lesions is discussed; fibrositis, sciatica, poliomyelitis and particularly neural leprosy must be excluded.

Fifty-one patients responded to treatment with vitamin B₁, and 6 recovered slowly on a full hospital diet without added vitamin B₁. The degree of recovery depended on the severity of muscular wasting or the extent and duration of sensory loss. Severe lesions were often crippling.

The etiology of the syndrome is discussed at length; the rations were supposed to provide 3 mg. vitamin B₁ daily, but appetites were poor and vegetarians were selectively affected. The form of onset and course and the response to vitamin B₁ suggested that the syndrome was atypical beriberi. The part played by fatigue also is discussed. It is suggested that fatigue may have contributed to the preponderance of right-sided lesions.—L. Wills.

ISERI, L. T., UHL, H. S. M., CHANDLER, D. E., BOYLE, A. J. and MYERS, G. B. **Fluid and electrolyte balance during recovery from high-output heart failure due to beri-beri.** *Circulation*, 1954, **9**, 247-254. [Dept. Med., Coll. Med., Wayne Univ., Detroit, Mich.] Spanish summary.

Detailed metabolic studies on 3 patients recovering from beriberi after long histories of chronic alcoholism showed that during recovery there was in each a great uptake of potassium by the cells, which in one was associated with sodium retention, and in two with significant loss of intracellular water. This movement of electrolytes during recovery was presumed to depend on osmotically active cellular base becoming inactive, which occurs also in low-output heart failure.

HÖÖK, O. **Polynuritis caused by hydrazide of isonicotinic acid. A report of 7 cases.** *Acta med. scand.*, 1953, **147**, 167-174. [Neurol. Clin., Serafimerlasaret, Stockholm.]

In the course of treatment with isonicotinic acid hydrazide, given alone or with *p*-aminosalicylate or dihydrostreptomycin, 7 patients with tuberculosis developed signs and symptoms of

N.A. and R., July 1954

peripheral neuritis. The daily dose used was from 6 to 10 mg. per kg. bodyweight in 6, and 5 mg. per kg. in the seventh. Symptoms appeared from 2 weeks to 3 months after the start of treatment. The first symptom to appear was paraesthesia of the soles of the feet, followed in some by loss of vibration sense, increased muscle reflexes in the lower limbs and hyperalgesia of the soles of the feet. The electromyogram was typical of a peripheral nerve lesion. The symptoms cleared up rapidly in most patients when the drug was withdrawn.—L. Wills.

3628

RÄTHÄ, C. E. and FORSANDER, O. **The cocarboxylase content of the blood in children.** *Acta paediat.*, 1953, **42**, 514–519. [Child. Clin., Univ. Helsinki.] French, German and Spanish summaries.

Cocarboxylase was estimated manometrically in the blood of 120 subjects aged from 0 to 25 years. The average value was higher in the younger children, decreased with age, particularly in the first year, and then remained constant after 7 years of age. The cocarboxylase content of cord blood from newborn infants was higher than in maternal blood, in which it was a little below the average for adults. The values were 8.1 μ g. per 100 ml. for maternal blood, 13.7 for full-term infants and about 10 for premature infants.

There was some correlation between erythrocyte count and cocarboxylase content, but there must also be some connection with the blood content of pyruvic acid, which decreases with age, and with the metabolism of which cocarboxylase is closely concerned.—V. R. Jackson.

3629

BOTTOLI, A. **La cocarbossilasi nel trattamento della neuriti da zoster. [Cocarboxylase in the treatment of herpes neuritis.]** *Arch. ital. dermatol.*, 1953, **25**, 453–456.

NICHELE, G. and SIGLIANTI, L. **Correlazioni inter-vitaminiche: influenza della cocarbossilasi sulla eliminazione urinaria di acido nicotinico e trigonellina. [Relations between vitamins: influence of cocarboxylase on the urinary excretion of nicotinic acid and trigonellin.]** *Arch. ital. Pediat. Puericoll.*, 1953, **16**, 263–283. [Ist. Clin. Pediat., Univ. Rome.] French, English and German summaries.

Nicotinic acid was estimated by the CNBr method, and trigonellin by the method of Roggen, in the urine of 15 children aged from 8 months to 11½ years, recovering from various diseases in hospital on a normal, complete diet. Nicotinamide, 100 mg., was given parenterally on 3

successive days, on the last 2 of which 50 mg. cocarboxylase also were given. The amount of nicotinic acid excreted in the urine in the 24 hr. after administration of nicotinamide was increased on the average by 5.57 mg. but, on the first day after cocarboxylase was given also, there was an average decrease below the initial value of 1.17 mg., and on the second day of 2.27 mg. The corresponding values for trigonellin excreted in the 24 hr. were increases of 13.39, 25.00 and 26.58 mg.

E. M. Hume.

3631

WALKER, A. R. P. **Low niacin concentration in the breast milk of Bantu mothers on a high-maize diet.** *Nature*, 1954, **173**, 405–406. [Human Biochem. Unit, S. African Inst. Med. Res., Johannesburg.]

Nicotinic acid and tryptophan were estimated microbiologically in breast milk from urban Bantu mothers in whose diet maize meal of from 90 to 100 per cent. extraction supplied up to 85 per cent. of the calories, from Indian and Eurafican mothers consuming small variable quantities of maize, from Bantu and Indian mothers on European diet, and from European mothers in comfortable circumstances. No difference due to race was found. Despite a higher intake of nicotinic acid, milk from Bantu mothers on the high-maize diet contained considerably less than that from Bantu mothers on European diet, the average being 70 μ g. per 100 ml. The mean values for the other 3 groups in the above order were 105, 150 and 175. The mean tryptophan contents in mg. per 100 ml. were 23 for Bantu and 21 for Europeans. The low nicotinic acid content of Bantu milk appeared to be due to abnormalities of metabolism associated with a high maize intake but further investigation is needed to determine the cause.

The low content of nicotinic acid in the milk had no apparent effect on the growth and health of the Bantu infants, which were comparable with those of European infants completely breast fed to 6 months of age.—V. R. Jackson.

3632

NOVAKOVSKAYA, A. A. and TIKHOMIROVA, A. N. **Izuchenie obmena nikotinovoi kisloty u bol'nykh dizenteriei. [Nicotinic acid metabolism in dysentery.]** *Vop. Pitan.*, 1954, **13**, No. 1, 15–21. [Kaf. Infektz. Bolezn., 1. Mosk. Ord. Lenin. Med. Inst.]

The excretion of N¹-methylnicotinamide in the urine and the level of dipyrindine nucleotide (D.P.N.) in the blood were studied in an attempt to estimate any change in the metabolism of nicotinic acid in 26 acute and 21 chronic cases of dysentery at 3 stages in the illness. Half the number of patients in each group had their diet

supplemented with curds, increasing its protein and tryptophan content. In acute cases without dietary supplement convalescence coincided with an appreciable fall in excretion of N¹-methylnicotinamide not found in chronic cases. D.P.N. levels in blood were little changed. In patients with a dietary supplement N¹-methylnicotinamide in urine reached lower, and D.P.N. in blood higher, levels than in those not given any supplement. Changes in total plasma protein and in albumin and globulin fractions also indicated benefit from the supplement.—D. W. Taylor.

3633

ANDREU URRA, J., RIVERO FONTAN, J. L. and ZOFFMANN, A. El componente hemolítico en la anemia de la pelagra. [The haemolytic component in the anaemia of pellagra.] *Rev. española Enferm. Apar. digest. Nutricion*, 1954, **13**, 3-5. [I. Clin. Med., Univ. Seville.]

Of 53 patients with pellagra 49 were found to be anaemic. Blood studies showed different forms of anaemia, but gave little or no evidence of haemolysis. In 7 of 8 patients who gave a positive reaction for urobilin in the urine, the anaemia was hypochromic and normocytic; in the other patient it was normochromic.

3634

CHLÁDEK, V. Léčení Menièrovy choroby látkami vysokého biologického účinku ze skupiny vitaminů. [Treatment of Menière's disease with a vitamin substance of high biological activity.] *Čas. Lék. čes.*, 1953, **92**, 1241-1245. [Otorhinolaryngol. Clin., Prague 12.] Russian and English summaries.

Lack of riboflavin was found in 45 per cent. of cases of Menière's disease, and lack of nicotinic acid was diagnosed from the state of the tongue in 50 per cent. Treatment with the two vitamins and with pyridoxine afforded considerable relief. Ascorbic acid was not found to confer any benefit. (From summary.)—E. M. Hume.

3635

COMACHO COMITRE, L. Determinación fluorométrica de riboflavinuria en mujeres aparentemente sanas y gestantes. [Fluorometric estimation of riboflavin in the urine of apparently healthy and of pregnant women.] *An. Fac. Farm. Bioquim., Lima*, 1952, **3**, 289-295. [Lab. Farmacol., Univ. Lima.]

Riboflavin was estimated by the method of Najjar (Abst. 2973, Vol. 11) in one-hour urine samples from 20 apparently healthy young women and from 20 pregnant women. The amounts of riboflavin excreted by the non-pregnant women varied from 0 to 50 μ g. [given as g.] per 10 ml.

urine with a mean value of 22.8 μ g. In pregnant women the values were lower, ranging from 0 to 18 μ g. per 10 ml. with a mean value of 4.5 up to the seventh month and 7.0 in the eighth and ninth months. The values are lower than those reported by other observers and suggest the possibility of riboflavin deficiency in the diet of the people of Lima.—A. M. Copping.

3636

JANSEN, A. P. and JANSEN, B. C. P. The riboflavin-excretion with urine in pregnancy. *Internat. Ztschr. Vitaminforsch.*, 1954, **25**, 193-199. [Netherlands Inst. Nutrit., Univ. Amsterdam.] French and German summaries.

Riboflavin was estimated chemically in 24-hr. samples of urine from 167 women between the second and ninth months of pregnancy. They were divided into 4 groups with estimated daily intakes of under 1.0 mg., 1.0 to 1.5 mg., 1.5 to 2.0 mg., and over 2.0 mg. Less than 5 per cent. had an intake of 2.5 mg., the recommended daily allowance of the [presumably U.S.] National Research Council. Results were compared with those for 82 samples from non-pregnant women aged from 20 to 40 years, of whom 24 per cent. had the recommended daily allowance of 1.5 mg.

There was no significant difference in riboflavin excretion between pregnant and non-pregnant women with an intake of less than 1.0 or more than 2.0 mg. With intakes of from 1.0 to 1.5 and from 1.5 to 2.0 mg., the differences in excretion were highly significant. For all groups taken together the excretion of riboflavin by the pregnant women was significantly less than by the non-pregnant women even when the intake of the former was considerably higher, which suggests an increased need during pregnancy.

Comparison of women in the first to third, fourth to sixth, and seventh to ninth months of pregnancy showed that the need was slightly increased during the first 3 months and greatly increased during the last 6. It is concluded that pregnant women need about 2.0 mg. daily.

The results are examined statistically.

3637

LUST, J. E., HAGERMAN, D. D. and VILLEE, C. A. The transport of riboflavin by human placenta. *J. Clin. Invest.*, 1954, **33**, 38-40. [Res. Lab., Boston Lying-in Hosp., Mass.]

Riboflavin was estimated by the photofluorimeter in the placenta and in maternal and cord blood obtained during 10 normal deliveries. The mean total riboflavin content of foetal serum was 3.70 μ g. per 100 ml., that of the maternal serum 3.07; the difference was due mainly to free riboflavin, of which the foetal serum had about 4 times

N.A. and R., July 1954

as much as the maternal serum. The flavin adenine dinucleotide content of maternal serum was about twice that of foetal serum. The placenta contained on the average 214 μ g. of total riboflavin per 100 g. wet tissue, of which 205 μ g. were flavin adenine dinucleotide and only 9 μ g. free riboflavin and riboflavin mononucleotide. The placenta was shown *in vitro* to contain a substance, presumably an enzyme, capable of splitting adenine dinucleotide to the mononucleotide and free riboflavin; it is suggested that it is the mechanism used in transferring riboflavin from mother to foetus.—L. Wills.

ALLEGRA, G. and NIUTTA, R. Ricerche sui bilanci e sulle relazioni di equilibrio di alcune vitamine (riboflavina, acido folico, vitamina B₁₂) in soggetti normali e in pazienti con sindromi intestinali croniche. 1. Il bilancio della riboflavina. [Studies of the balance and equilibrium relationships of some vitamins (riboflavin, folic acid, vitamin B₁₂) in normal subjects and patients with chronic intestinal disturbances. 1. Riboflavin balance.] *Acta vitaminol.*, 1953, 7, 246-252. [Ist. Clin. Med. Gen., Univ. Messina.] French, English, German and Spanish summaries.

Subjects were maintained for 5 days on a standard diet containing about 0.35 mg. riboflavin per 1000 Cal. After fasting for 16 hr. they were given 2 mg. riboflavin intravenously, and were kept fasting for a further 24 hr., during which urine was collected. The same procedure was followed without injection of riboflavin. Riboflavin was estimated fluorimetrically. In 5 healthy subjects the mean percentage of the test dose excreted in the first 24 hr. was 56, the peak of elimination being reached in the first half-hour. In 13 subjects with chronic intestinal disorders and no sign of riboflavin deficiency the mean percentage was 41, and in 10 similar subjects but with signs of riboflavin deficiency it was 33. The peak of excretion in both groups was in the first hour.—E. M. Hume.

3639

BARBIERI, L. L. and BRUNELLI, M. A. Contributo allo studio delle variazioni del metabolismo glucidico indotte dalla riboflavina e dal suo estere monofosforico. [Changes in carbohydrate metabolism induced by riboflavin and its monophosphate ester.] *Internat. Ztschr. Vitaminforsch.*, 1954, 25, 157-169. [Ist. Clin. Med., Univ. Bologna.] English, French and German summaries.

Sugar and pyruvic and lactic acids were estimated in the blood of 10 healthy persons and 12 patients with cardiac decompensation before and

1, 2 and 3 hr. after intravenous administration of 20 mg. riboflavin or its monophosphate ester, alloxazine mononucleotide.

The effect on blood sugar of either substance was small. In both healthy subjects and patients there was a small increase in the first hour after riboflavin, and a longer delayed, small increase after the ester.

The value for blood pyruvic acid after administration of either substance rose in the healthy subjects, with the peak in the first hour. In the patients it was not consistently affected after riboflavin, but rose as in the healthy subjects after the ester.

The value for blood lactic acid fell in the healthy subjects after riboflavin or the ester, the value usually being lower in the third hour than in the first. In the patients the response to riboflavin was irregular; all except one showed a reduction at some time, but the decrease might be greatest in the first, second or third hour. The response to the ester was usually a progressive decrease.

It is concluded that in patients with cardiac decompensation the phosphorylation of riboflavin is disturbed.—E. M. Hume.

3640

BOLDRINI, R. and MONTENERO, P. Eliminazione urinaria della lattoflavina totale in corso di scompenso cardiaco. 2. Influenza della cocarbossilasi sulla lattoflavinuria degli scompensati. [Urinary excretion of riboflavin in cardiac decompensation. 2. Effect of cocarboxylase on the urinary riboflavin in cardiac decompensation.] *Acta vitaminol.*, 1954, 8, 3-6. [Ist. Clin. Med., Univ. Rome.] French, English, German and Spanish summaries.

For Part 1 see Title 3477, Vol. 23.

Riboflavin was estimated in the urine of 6 patients with cardiac decompensation, treated with digitalis, before and after a single intravenous injection of 100 mg. cocarboxylase. The value fell immediately after the injection by a percentage ranging from 24 to 35, and returned to the initial value in 3 days.—E. M. Hume.

3641

BENEDETTI, A. Segni di ariboflavinosi in corso di cirrosi epatica. Presenza di riboflavina nell'ascite. [Signs of riboflavin deficiency in the course of liver cirrhosis. Presence of riboflavin in the ascitic fluid.] *Acta vitaminol.*, 1953, 7, 260-264. [Ist. Clin. Med., Univ. Modena.] French, English, German and Spanish summaries.

An account is given of 3 patients with liver cirrhosis and ascites, which had necessitated frequent tapping. All had tongue changes characteristic of riboflavin deficiency.

Riboflavin was estimated fluorimetrically in ascitic fluid and pleural exudates of 10 patients. The concentration ranged from 20 to 150 μg . per litre. The loss of riboflavin by tapping is considered to be possibly of significance.

ESCHE, H. Stottern—Symptom einer Hypovitaminose. [Stammering as sign of a vitamin deficiency.] *Münch. med. Wochenschr.*, 1953, **95**, 1135. [Sebexen über Kreinsen.]

A favourable preliminary result was obtained when stammering children aged from 4 to 9 years were treated with B vitamins as 25 drops Polyvital daily.—E. M. Huime.

3643

STANGL, E. Studien über den Einfluss der Pantothenensäure auf den Blutzucker des Menschen. [Effect of pantothenic acid on blood sugar in man.] *Internat. Ztschr. Vitaminforsch.*, 1954, **25**, 135–138. [Med. Klin., Univ. Innsbruck.] French and English summaries.

Intravenous injection of from 100 to 500 mg. pantothenic acid reduced the fasting blood sugar value in 10 subjects tested at an altitude of about 5000 ft. At 1800 ft. also the blood sugar value fell in 3 diabetic subjects, but in 6 healthy subjects and one with diabetes insipidus the value rose in response to a dose of 500 mg. pantothenic acid. In discussing the observations it is suggested that pantothenic acid may affect the beta cells of the islets of Langerhans.—A. M. Copping.

3644

HART, P. L. DE V. Carcinoma complicated by proximal motor neuropathy due to vitamin-B deficiency. *Brit. Med. J.*, 1954, i, 606–609. [Royal Cancer Hosp., London.]

Two types of neuropathy associated with cancer are reported, one chronic, peripheral, and associated with sensory symptoms, and one affecting the proximal musculature, with few sensory symptoms and sometimes with rapid and severe involvement of the brain stem. Two cases of the latter type are reported. One patient improved dramatically under treatment with the vitamin B complex and there was suggestive evidence that the neuropathy was improved by administration of pyridoxine or pantothenic acid; associated myocardial weakness responded to vitamin B₁. In the other patient great muscle weakness improved with pyridoxine. It is suggested that the symptoms develop as a result of competition for the vitamins by the tumour cells.—L. Wills.

3645

NEUWEILER, W. and FISCHER, H. Über das Vitamin B₆ in der Frauenmilch. [Vitamin B₆

in human milk.] *Internat. Ztschr. Vitaminforsch.*, 1954, **25**, 205–209. [Frauenklin., Univ. Berne.] English and French summaries.

Vitamin B₆ was estimated microbiologically with *Saccharomyces carlsbergensis* and a mutant of *Neurospora sitophila*. The amounts found, in μg . per 100 ml., were from 15 to 20 in human milk and 120 in cow's milk. Oral administration of 60 mg. vitamin B₆ daily for 3 days caused a marked rise in the amount in the milk. The values fell again 6 to 9 hr. after a single dose and after 3 days even if the vitamin was continued.—A. M. Copping.

3646

MOLONY, C. J. and PARMELEE, A. H. Convulsions in young infants as a result of pyridoxine (vitamin B₆) deficiency. *J. Amer. Med. Assoc.*, 1954, **154**, 405–406. [Child. Hosp., Los Angeles, Calif.]

A peculiar disorder occurring in young infants, characterised by epileptiform convulsions not associated with any other sign of illness or with laboratory findings suggesting any etiological cause, was reported first from scattered areas and finally from all parts of the country. The one thing common to all was that the infants had been artificially fed on a liquid milk preparation, SMA. Six infants, all aged from 2 to 3 months, were studied in hospital. In 5 of them, an encephalogram recorded at the time of convulsions showed mild or diffuse abnormality. The infants all remained free from convulsion on hospital diet. The condition is attributed to lack of vitamin B₆ in the SMA preparation. Changes which had been made in the manufacture of SMA were use of palm oil in place of coconut oil and introduction of a different method of sterilisation in the can.

COURSIN, D. B. Convulsive seizures in infants with pyridoxine-deficient diet. *J. Amer. Med. Assoc.*, 1954, **154**, 406–408. [Dept. Paediat., St. Joseph's Hosp., Lancaster, Pa.]

Four infants were admitted to hospital with convulsive seizures which had developed when the babies were from 5 weeks to 4 months of age. The electro-encephalogram showed no clear abnormality between seizures. A change of food or sedatives prevented the fits. The case histories showed that all had been fed from birth on the liquid milk preparation SMA. A test of SMA showed that it contained only 60 μg . pyridoxine per litre, and included a vitamin preparation containing no pyridoxine. In another infant with a similar history, the electro-encephalogram during a fit was abnormal and there were occasional outbursts of a high-pitched, monotone cry; 3 min. after the intramuscular injection of 100 mg. pyridoxine there was reduced activity in the en-

cephalogram, which after 4 to 5 min. became normal. This infant subsequently remained well and developed normally on the same SMA preparation supplemented with pyridoxine. Another 50 cases subsequently came to the author's attention.

HUNT, A. D. (JR.), STOKES, J. (JR.), MCCRODY, W. W. and STROUD, H. H. **Pyridoxine dependency: report of a case of intractable convulsions in an infant controlled by pyridoxine.** *Pediatrics*, 1954, **13**, 140-145. [Child. Hosp., Philadelphia, Pa.] Spanish summary.

Severe convulsions occurred in an infant 3 hr. after birth and continued in spite of treatment until a vitamin preparation containing pyridoxine was given. Similar convulsions which proved fatal in 30 hr. had occurred in a previous child. During both pregnancies the mother had been treated for severe *hyperemesis gravidarum* with large doses of pyridoxine. An earlier normal pregnancy had resulted in a normal child. Clinical trial showed that 2 mg. pyridoxine daily, given orally, controlled the fits; after the withdrawal of the drug fits reappeared in about 50 hr. Electroencephalographic studies showed marked dysrhythmia and slow wave activity when a fit was developing; these abnormalities persisted but were less obvious 15 min. after pyridoxine had been given. Excretion of xanthurenic acid after administration of tryptophan showed no evidence of pyridoxine deficiency in mother or child. At 20 months, although the child had had continuous treatment, it was mentally retarded. It is suggested that the infant had an anomaly of pyridoxine metabolism and that the fits were not due to simple deficiency.—L. Wills.

3649

GONZÁLEZ MENÉNDEZ, E. La vitamina B₆ frente a la involucion senil. [Vitamin B₆ against senile decay.] *Rev. clín. española*, 1953, **51**, 112-114. [Oviedo.] English, German and French summaries.

Literature on the clinical use of vitamin B₆ in Parkinson's disease and other nervous and muscular disorders is discussed. Treatment with pyridoxine was given to 5 patients with senile tremor associated with unsteady gait, insomnia, asthenia and general impairment of faculties. A daily oral dose of 0.08 g. with intramuscular injection of 0.05 g. every second day for 24 days produced a sensation of euphoria and general well-being; tremor and unsteadiness improved within a week. The effect of vitamin B₆ in senile patients was considered to be better than that of androgens, and it is suggested that the vitamin had a direct effect on nerve centres.—A. M. Copping.

WACHSTEIN, M. and GUDAITIS, A. **Disturbance of vitamin B₆ metabolism in pregnancy. 3. Abnormal vitamin B₆ load test.** *Amer. J. Obstet. Gynecol.*, 1953, **66**, 1207-1213. [Labs., St. Catherine's Hosp., Brooklyn, N.Y.]

After an oral test dose of 25 mg. pyridoxal hydrochloride the 4-pyridoxic acid excreted in the next 8 hr. was estimated fluorimetrically. The mean excretion in mg. in the 8 hr. before the test was 0.85 ± 0.07 in 20 normal subjects and 0.74 ± 0.07 in 10 pregnant normal women. The mean amount excreted in the test by 20 normal subjects was 11.55 ± 0.25 ; in 22 patients of both sexes with a variety of diseases it was 11.15 ± 0.29 ; in 42 normal pregnant women at term and in 14 pregnant women suffering from toxæmia the mean excretion was only 8.84 ± 0.33 and 8.53 ± 0.37 mg., respectively, values significantly below the means for the normal groups. The results confirmed those of the DL-tryptophan test (Abst. 1104, Vol. 24) and are taken as a sign of vitamin B₆ deficiency in pregnancy.—L. Wills.

3651

WEIR, D. R. and MORNINGSTAR, W. A. **The effect of pyridoxine deficiency induced by desoxy-pyridoxine on acute lymphatic leukemia of adults.** *Blood, J. Hematol.*, 1954, **9**, 173-182. [Crile Vet. Admin. Hosp., Cleveland, Ohio.]

Four patients were treated while on normal hospital diet with desoxypyridoxine in divided oral doses which ranged from 600 to 1400 mg. daily. Seborrhoeic dermatitis, a sign of pyridoxine deficiency, developed with doses of 1000 mg. or more after from 16 to 18 days; no other sign occurred. In all 4 patients there was a fall in the number of immature lymphoid cells in the peripheral blood; in 1 only there was also an increase in the number of granulocytes in both blood and bone marrow, and in 2 post-mortem examination of the tissues showed some modification of the usual lymphatic infiltration. A partial temporary clinical remission was seen in 2 patients but after relapse further treatment was ineffective. All 4 patients died. Post-mortem examination of 3 showed degeneration of the adrenal cortex in all and in 2, crystalline deposits in the convoluted tubules of the kidney; there was no massive haemorrhage.—L. Wills.

3652

GRINSCHGL, G. and BLAŽEVIĆ, D. Vitamin B₆ i histamin (Izvod). [Vitamin B₆ and histamine.] *Acta med. jugoslav.*, 1953, **7**, 227-246. [Psychiat. Neurol. Klin., Univ. Graz.] In German: Serbian summary.

A subcutaneous injection of 1 ml. of 0.1 per cent. histamine phosphate was made into the arm

of 20 human subjects. Blood pressure and characteristic reactions to histamine were recorded before and after the injection. For the next 5 days an intramuscular injection of 200 mg. vitamin B₆ was given daily, and on the sixth day the same amount was injected intravenously. Thirty min. later the histamine test was repeated. In 8 of the subjects the reaction to histamine was less after administration of vitamin B₆, in 9 there was no difference, and in 3 the reaction was greater. When histamine was given in the same way but without vitamin B₆ in the intermediate period, there was no difference in the response to the first and second injections.

Daily treatment for 6 days with 200 mg. vitamin B₆ had no effect on the skin reaction to histamine in human subjects.

Of 2 groups of 20 guineapigs given an injection of 14 mg. per kg. bodyweight of histamine as the phosphate, one group was given 50 mg. vitamin B₆ for 6 days previously. Of the animals given vitamin B₆, 8 died and of those not given it 14; the signs of shock also were less in the survivors of those given vitamin B₆.—E. M. Hume.

3653

KAUFFMAN, S. L., KASAI, G. J. and KOSER, S. A. **The amounts of folic acid and vitamin B₆ in saliva.** *J. Dent. Res.*, 1953, **32**, 840-849. [Walter G. Zoller Mem. Dent. Clin., Univ. Chicago, Ill.]

Folic acid and vitamin B₆ were estimated in fresh saliva by microbiological methods with oral strains of lactobacilli as test organisms. The amount of folic acid ranged from 0.003 to 0.075, average 0.024, $\mu\text{g. per ml.}$, for 51 samples of saliva from 20 young adults. The average value for vitamin B₆ with pyridoxal hydrochloride as standard was 0.006 $\mu\text{g. per ml.}$, with a range from 0.001 to 0.017, for 52 samples from 17 subjects. The reliability of the tests is discussed and the relationship of the vitamin content of the saliva to the growth and acid production of lactobacilli in the mouth is considered.—A. M. Copping.

PEÑA, E. F. **Prevention of abortion.** *Amer. J. Surg.*, 1954, **87**, 95-96. [Miami, Fla.]

Ninety multiparae with a history of from 1 to 7 miscarriages and 20 with no such history, and 90 primiparae, were given during pregnancy an oral preparation containing stilboestrol, vitamin C and the vitamin B complex, including vitamin B₁₂ and folic acid. There were only 2 abortions, both in women with a history of miscarriages. The amount given varied, large doses being used when there was a history of miscarriages or when signs of threatening abortion were present. The dose

was increased also at the periods when menstruation would have occurred. The treatment was well tolerated.—L. Wills.

BARBAGALLO - SANGIORGI, G. and CAJOZZO, A. **Studio sulle modificazioni citochimiche indotte dalla somministrazione di vitamina B₁₂, a dosi elevate, sugli elementi del midollo osseo in soggetti non anemici perniciosi.** [Cytochemical changes, caused by giving large doses of vitamin B₁₂, in the bone marrow of subjects without pernicious anaemia.] 1. Comportamento degli acidi desossi e ribo-nucleinici. [1. Behaviour of ribonucleic and deoxyribonucleic acid.] 2. Comportamento dei lipidi. [2. Behaviour of fats.] 3. Comportamento dei polisaccaridi. [3. Behaviour of polysaccharides.] *Boll. Soc. ital. Biol. sper.*, 1953, **29**, 1074-1075; 1076-1078; 1078-1081. [Ist. Clin. Med., Univ. Palermo.]

1. Specimens of bone marrow from normal subjects before and after treatment were stained for ribonucleic acid by the method of Unna and Pappenheim as modified by Brachet, and for deoxyribonucleic acid by the method of Feulgen. In subjects given 50 $\mu\text{g.}$ vitamin B₁₂ daily for from 4 to 6 days, no change was seen. In other subjects

N.A. and R., July 1954

given the same dose for from 20 to 40 days, or given 500 μ g. daily for 3 or 6 days, there was no increase of deoxyribonucleic acid, but there was increased mitotic activity, growth of nuclei and nucleoli, and increase in the ribonucleic acid content of the cytoplasm of immature red and white cells.

2. In the same subjects treated in the same way, the bone marrow preparations were stained with Sudan black B and Giemsa. In the subjects given the small dose for the short period, there was no change in the lipid staining of the marrow cells, but in a good many of the other subjects there was a decrease in lipid staining in the cytoplasm of the most immature of the granuloblast series of white cells.

3. Marrow smears from the same subjects, treated in the same way, were examined for polysaccharides by a method based on reaction with periodic acid, the exact specificity of which was, however, doubtful. In the subjects more intensively treated with vitamin B₁₂ there was a small increase in the reaction in promyelocytes, myelocytes, metamyelocytes and granulocytes. The substance responsible was possibly glycogen.

DAS GUPTA, C. R., CHATTERJEA, J. B. and BASU, P. Vitamin B₁₂ in macrocytic anaemia in pregnancy. *Indian Med. Gaz.*, 1953, **88**, 102-105. [Dept. Haematol., Sch. Trop. Med., Calcutta.]

In 21 patients with macrocytic anaemia during pregnancy or the puerperium, 13 of them with megaloblastic marrow and 8 with normoblastic marrow, there was a poor response or none to

small oral doses of vitamin B₁₂, but in the majority there was a good initial response, associated with a suboptimum reticulocyte crisis, after parenteral treatment irrespective of the state of the marrow. The initial response was not maintained but the patients later responded to folic acid or a crude liver extract. Some of them were delivered during treatment, which made assessment of the results difficult.—L. Wills.

FOY, H. and KONDI, A. The haematinic action of penicillin in megaloblastic anaemia and its relationship to B₁₂ metabolism and the intestinal flora. *Trans. Roy. Soc. Trop. Med. Hyg.*, 1954, **48**, 17-35 (with discussion 36-41). [Wellcome Trust Res. Labs.]

In extension of previous work on megaloblastic anaemia in Kenya Africans the present report deals with 24 patients, all apparently well nourished and of good physique, who were admitted with severe megaloblastic anaemia. After a period of from 4 to 10 days without treatment they were given daily for from 7 to 17 days 200,000 units of penicillin orally or 400,000 units by intramuscular injection; 8 failed to respond and of these, 4 failed to respond to 88 μ g. vitamin B₁₂ given orally but responded to the same dose given parenterally; 4 failed to respond to vitamin B₁₂ but responded to folic acid. The 4 who responded to vitamin B₁₂ given parenterally had gastric atrophy, but not the 4 who responded to folic acid. It is suggested that penicillin is not an active haematinic substance but exerts its effect in the gut.

A brief review is given of the earlier clinical tests of the potency of anti-anaemia preparations and of the definition of a unit of liver activity. Preparations of folic acid require to be labelled only with the amount of folic acid present. Since the isolation of vitamin B₁₂ and the development of methods of microbiological estimation, a standard microbiological method has been used to determine the vitamin B₁₂ content of refined and crude U.S.P. liver preparations, and such preparations are now labelled with their vitamin B₁₂ content in μ g. Considerable variation was found in the vitamin B₁₂ activity of products with the same activity in U.S.P. units, so that it was not possible to compute a factor for converting U.S.P. units into microgram equivalents of the vitamin. Official, parenteral preparations of refined liver extract contain 10 or 20 μ g. of vitamin B₁₂ per ml., and of crude liver extract 1 or 2 μ g. per ml. The U.S.P. unit (oral) content must be decided by clinical tests.

LATNER, A. L., MERRILLS, R. J. and RAINE, L. C. D. P. **Isolation of Castle's intrinsic factor.** *Lancet*, 1954, **266**, 497-498. [Dept. Pathol., King's Coll., Univ. Durham, Newcastle upon Tyne.]

Material obtained directly from gastric mucosa by methods to be reported later was soluble at pH 2.0. It was highly active in reducing the faecal excretion of vitamin B₁₂. It was examined by paper strip electrophoresis, with the ultracentrifuge, and analytically. With the ultracentrifuge, it was shown to contain a small amount of protein of high molecular weight which sedimented rapidly and left an apparently homogeneous material, representing about 95 per cent. of the original material; the molecular weight by the ultracentrifuge was below 20,000. By analytical methods the molecular weight was found to be of the order of 15,000. The material thus obtained and that obtained previously by electrophoresis were similar in biological activity, chemical structure and behaviour during electrophoresis; these facts and the results obtained with the ultracentrifuge are considered evidence of chemical purity.—L. Wills.

CALLENDER, S. T., TURNBULL, A. and WAKISAKA, G. **Estimation of intrinsic factor of Castle by use of radioactive vitamin B₁₂.** *Brit. Med. J.*, 1954, **i**, 10-13. [Nuffield Dept. Clin. Med., Radcliffe Infirmary, Oxford.]

A standard oral dose of 0.5 μ g. of a radio-active vitamin B₁₂ preparation of high specific activity (420 μ C. per mg.) contained approximately 0.2 μ C. radio-activity. In 10 subjects haematologically normal except for one who had hypochromic anaemia, an average of 31.0 per cent. of the radio-activity of the test dose was lost in the faeces; in the presence of infection the percentage was greatly increased. In 11 patients with pernicious anaemia in remission and in 2 patients in relapse the mean loss was 88.7 per cent.; when the test was repeated with the same dose of vitamin B₁₂ but with some source of intrinsic factor added the radio-activity of the faeces was greatly reduced, the amount of the change varying with the potency of the source of intrinsic factor.

SPIES, T. D., STONE, R. E., SUAREZ, R. M., GARCIA-LOPEZ, G., LOPEZ-TOCA, R. and REBOREDO, A. **Antianemic properties of reaction products of vitamin B₁₂ and the intrinsic factor.** *J. Amer. Med. Assoc.*, 1953, **151**, 1264-1266. [Dept. Nutrit., Northwestern Univ. Med. Sch., Chicago, Ill.]

Eight patients with pernicious anaemia in relapse, 2 with tropical sprue and macrocytic anaemia, and 1 with nutritional macrocytic anaemia, the last three with free HCl in their gastric juice, were treated orally for from 10 to 15 days with from 10 to 15 μ g. crystalline vitamin B₁₂ daily; none responded clinically or haematologically. The vitamin B₁₂ preparation was then replaced by one containing the same daily dose of the vitamin, together with a source of intrinsic factor. All the patients responded both clinically and haematologically, but the response by those with sprue and nutritional macrocytic anaemia was not as full as by the patients with pernicious anaemia. Three patients known to respond poorly to vitamin B₁₂, given orally either alone or after incubation with normal gastric juice, did not respond to the dose of the combined preparation used in the previous trial, though they responded fully to 10 μ g. of the vitamin by intramuscular injection. Another study of 11 patients with sprue and anaemia confirmed that they were more resistant than patients with pernicious anaemia to combined preparations given orally. The combined preparation used was active after boiling for 30 min.—L. Wills.

3675

SCHILLING, R. F. **Intrinsic factor studies. 2. The effect of gastric juice on the urinary excretion of radioactivity after the oral administration of radioactive vitamin B₁₂.** *J. Lab. Clin. Med.*, 1953, **42**, 860-866. [Dept. Med., Med. Sch., Univ. Wisconsin, Madison.]

In normal subjects an appreciable amount of radio-activity appeared in the urine after an oral dose of 2 μ g. vitamin B₁₂ ⁶⁰Co followed 2 hr. later by 1000 μ g. of non-radio-active vitamin B₁₂ given subcutaneously; in patients with pernicious

anaemia in remission only traces of radio-activity were detected after such treatment, but administration of normal gastric juice with the labelled vitamin produced an excretion of the same order as that in normal subjects. Boiling the gastric juice before use prevented the appearance of activity in the urine. The administration of terramycin did not increase the radio-activity of urine after the test doses in a patient with pernicious anaemia. No radio-activity could be detected in the urine when the subcutaneous "flushing" dose of non-active vitamin B₁₂ was omitted. The author considered that his results supported the view that the intrinsic factor promotes the absorption of vitamin B₁₂ in patients with pernicious anaemia.—L. Wills.

ISRAËLS, M. C. G. and SHUBERT, S. **The treatment of pernicious anaemia by insufflation of vitamin B₁₂.** *Lancet*, 1954, **266**, 341-343. [Dept. Haematol., Univ. Manchester.]

Four patients with untreated pernicious anaemia and one patient with pernicious anaemia in remission were successfully treated with vitamin B₁₂ snuff which was blown into the nose and inhaled. The dose used was 100 μ g. from one to three times daily at first and twice weekly for maintenance; such doses were well tolerated locally. The expense of such treatment compares very favourably with that of oral treatment with tablets containing vitamin B₁₂ and intrinsic factor.

BASTRUP-MADSEN, P. **Non-anaemic neuropathy caused by deficiency of the anti-pernicious-anaemia principle following subtotal gastrectomy.** *Acta med. scand.*, 1953, **147**, 399-404. [Dept. Med., Marselisborg Hosp., Aarhus.]

Nerve signs developed in 2 patients who had undergone subtotal gastrectomy. In one, signs of peripheral neuritis appeared 2 months after the operation, and 12 months later the posterior columns of the cord were seriously affected, but in the other, 13 years elapsed before signs appeared,

and then they were only those of peripheral neuritis. The blood and bone marrow findings were normal in both patients. Parenteral treatment with vitamin B₁₂ resulted in complete cure.

BASTRUP-MADSEN, P. The cytology of the bone marrow in pernicious anaemia with normal haemoglobin level. Glossitis and subacute combined degeneration of the spinal cord due to deficiency of the anti-pernicious-anaemia principle. *Acta med. scand.*, 1954, **148**, 13-26. [Dept. Med., Marselisborg Hosp., Aarhus.]

Blood and bone marrow were examined and gastric juice was analysed from 7 patients with chronic glossitis and signs of subacute combined degeneration of the cord and from 1 patient with nerve signs only. In all, the Hb value was normal, but the red cell count was slightly low in most, so that the colour index was high, a finding suggestive of pernicious anaemia. Further evidence in support of the diagnosis was the presence of abnormal giant neutrophils in the bone marrow of every patient and of intermediate megaloblasts in the bone marrow of some. Every patient had histamine-fast achlorhydria. After treatment with liver extract or vitamin B₁₂ the glossitis and the neurological signs improved or disappeared, and the blood and marrow became normal. It is concluded that for diagnosis of such latent pernicious anaemia, examination of the bone marrow is essential.—L. Wills.

SURTEES, S. J. and HUGHES, R. R. Treatment of trigeminal neuralgia with vitamin B₁₂. *Lancet*, 1954, **266**, 439-441. [Royal Southern Hosp., Liverpool.]

Treatment with massive intramuscular doses of vitamin B₁₂ was given to 18 patients with trigeminal neuralgia and to 1 with glossopharyngeal neuralgia; in 15 of the former and in the latter there was symptomatic improvement, generally sudden in onset, which varied from complete relief to definite improvement. A generally suitable course of treatment was 1 mg. daily for 10 days followed by 5 injections of the same dose twice a week. Relapses occurred but the patients responded to further courses of treatment.

N.A. and R., July 1954

[Treatment of diabetic polyneuritis with vitamin B₁₂.] *Klin. Wochenschr.*, 1953, **31**, 960-961. [I. Med. Klin., Univ. Hamburg, Eppendorf.]

In 18 patients with diabetic polyneuritis of varying duration, a daily dose of 60 µg. vitamin B₁₂ for 10 days produced no improvement, but when the dose was increased to 1000 µg. daily most of the patients improved and, after 2 or 3 days, had less pain and paraesthesia. Later there was improvement in the hyperaesthesia, hyperalgesia and burning of the soles of the feet; often the cramp in the calves improved also. There was no improvement in the abnormal reflexes or in the signs related to the vegetative nervous system, possibly owing to the shortness of the observation period.

VITAMIN C SUBCOMMITTEE OF THE ACCESSORY FOOD FACTORS COMMITTEE, MEDICAL RE-

Vol. 24, No. 3

SEARCH COUNCIL, AND OTHERS. **Vitamin C requirement of human adults**. *Med. Res. Council. Spec. Rep. Ser. No. 280*, 1953, pp. viii + 179 + 24 plates. Price 17s. 6d. net. H.M.S.O., London.

The Report is the full account of the study briefly reported earlier (Abst. 2449, Vol. 18). A short historical account is given of other experiments on vitamin C deprivation in man. There is a full account of the main experiment. Fifteen special aspects of the experiment are elaborated separately; they include results of saturation tests, exercise-tolerance tests, capillaroscopy, and haematological investigation. Details of methods are given in full, and there are case histories of all the 20 volunteers. Tables give for each subject all the individual results of estimations of vitamin C in plasma, whole blood and white cells, of blood urea, proteins and phosphatase, and of vitamin C in the urine. There are long series for vitamin C content of the same material by several different methods. Other data which were too voluminous for publication can be obtained as microfilms. There are 6 coloured plates of scorbutic lesions, and 18 uncoloured ones.—E. M. Hume.

[Comparison between plasma values and the results of saturation tests at different levels of vitamin C intake]**. *Internat. Ztschr. Vitaminforsch.*, 1954, **25**, 186-193. [Abt. Hyg., Univ. Reykjavik.] English and French summaries.

The mean blood plasma ascorbic acid value of pupils in a boarding school was 0.57 mg. per 100

ml. in October, 0.31 in February, 0.16 in May and 0.11 in June. The average dietary intake was from 40 to 50 mg. in autumn, 35 to 30 mg. in winter and 20 to 23 in spring. Loading tests with 10 mg. ascorbic acid per kg. bodyweight daily showed that saturation was reached after 2 days in the autumn but required several days at other times. It is concluded that the plasma ascorbic acid value is a better index of dietary intake than the results of saturation tests.—W. Godden.

MERROW, S. B., LAMDEN, M. P., PIERCE, H. B., NEWHALL, C. A., CHRYSTOWSKI, G. A. and DURBROW, A. B. **Relationships between physical signs of deficiency, blood levels, and food intakes with respect to vitamin A and ascorbic acid in selected groups of children.** *J. Clin. Nutr.*, 1953, 1, 517-527; 528-533. [Dept. Biochem., Coll. Med., Univ. Vermont.] Spanish summaries.

Schoolchildren under 12 years of age were examined for physical signs of deficiency of vitamins A and C. Three groups, each of 25 children, were selected according to certain criteria as deficient in vitamin A, deficient in vitamin C, or normal. The signs of vitamin A deficiency were taken as thickening of the bulbar conjunctiva, follicular hyperkeratosis, and dryness, crinkling and scaling of the skin. The signs of vitamin C deficiency were taken as abnormalities of the gums, skin, eyes, tongue and lips, and in resistance to bleeding. Statistical studies were made on the rate of incidence of these abnormalities in each group, and of the frequency with which pairs or groups of abnormalities occurred together. On using incidence only of the signs, a majority of the normal group could have been included in a deficient group since they had one or more of the signs associated with vitamin A or vitamin C deficiency. When degree of severity was noted as well as incidence, group differences became apparent and the use of combinations of signs together with incidence and severity defined the 3 groups.

Vitamin A, carotene and ascorbic acid were estimated chemically in the autumn of 1949 and the spring of 1950, in the blood of children divided, as described above, into a normal group, and groups showing signs of deficiency of vitamins A and C. Only small differences were found in vitamin A values between the vitamin-A-deficient and the normal group, and in ascorbic acid values between the vitamin-C-deficient and the normal group. A greater disparity was found between

the carotene values in the vitamin-A-deficient and the normal groups, the respective values, in $\mu\text{g.}$ per 100 ml., being 127 and 161 in the autumn, and 137 and 186 in the spring. The relationships between the values for vitamins A and C and carotene in the blood and the records of dietary intakes were suggestive but irregular.—T. Moore.

[Landeskinderheilstätte Mammols Höhe, Taunus.]

Wide differences occur with variety in the ascorbic acid content of fruit and vegetables, particularly of apples. To test whether such differences are reflected in the biological activity of the fruits, feeding experiments were made with groups of guineapigs on a diet low in vitamin C to which differing amounts of 2 varieties of apples, one containing 20.6 and the other 3.1 mg. ascorbic acid per 100 g., were added. With 10 g. daily of the second there was no protection from scurvy, but with 2 g. of the first protection was complete.

In an experiment with 39 children aged from 4 to 16 years, recovering from tubercular disease, the blood vitamin C value before the beginning of the experiment was near the level in scurvy although the children had been on a diet containing adequate fruit and vegetables. The relative response in blood and urine of the children to supplements of the 2 varieties of apples given for 3 weeks reflected the result obtained in the animal experiment. In human diets, therefore, attention should be paid to quality rather than quantity of fruits and vegetables, and in hospitals, sanatoria, children's homes and community feeding centres there should be control by chemical analysis.

LUGG, J. W. H. and ELLIS, F. P. **Some water-soluble vitamins in the sweat of tropically acclimatized European men.** *Brit. J. Nutrition*, 1954, **8**, 71-77. [Dept. Biochem., Univ. Malaya, Singapore.]

Healthy European men aged from 20 to 40 years who had lived in a warm, moist, tropical climate for $1\frac{1}{2}$ to $4\frac{1}{2}$ years did work in a climate considerably warmer than the normal Singapore climate. The arms were encased and sweat was collected for from 20 to 40 min. The subjects drank freely during and after the exercise and in some cases took 4 doses of 125 mg. L-ascorbic acid at regular intervals during the 26 hr. beforehand. Ascorbic acid and dehydroascorbic acid were estimated in sweat and urine, and vitamin B₁ in sweat. Ascorbic acid was estimated by Lugg's method (Abst. 260, Vol. 13), vitamin B₁ by that of Friedemann and Kmiecik (Abst. 2536, Vol. 13).

The concentration of ascorbic acid and dehydroascorbic acid together did not exceed 0.05 mg. per 100 ml. sweat and was generally less or negligible; no serious loss could thus occur even in 10 litres of sweat daily if the intake were normal, but subjects with a low intake could become depleted over a period of time. In more precise estimations the average content in mg. per 100 ml. was for ascorbic acid 0 and for dehydroascorbic acid 0.02. The results differ somewhat from those obtained by other workers (Kirch *et al.*, *Proc. Soc. Exp. Biol. Med.*, 1943, **54**, 307; Shields *et al.*, Abst. 3647, Vol. 15) and the reasons for discrepancy are discussed. The administration of 500 mg. L-ascorbic acid before exercise had no significant effect.

Administration of ascorbic acid increased the urinary output about 7 times but the output of dehydroascorbic acid did not appear to be significantly affected. Since dehydroascorbic acid was converted spontaneously to diketogulonic acid, especially in urine of high pH value, the urinary loss may have been appreciably greater.

Excretion of vitamin B₁ in sweat was 0.123 mg. per 100 ml.—V. R. Jackson.

LAMDEN, M. P. and CHRYSTOWSKI, G. A. **Urinary oxalate excretion by man following ascorbic acid ingestion.** *Proc. Soc. Exp. Biol. Med.*, 1954, **85**, 190-192. [Dept. Biochem., Coll. Med., Univ. Vermont, Burlington.]

The mean 24-hr. urinary excretion of oxalic acid by 51 healthy men on a normal diet was 38.3 ± 1.7 mg., the value for any one individual being remarkably constant over a 3-week period. The men were divided into groups, some of which received daily for one week 0.25, 0.5, 1, 2, 4 or 8 g. ascorbic acid given in 3 portions. The ingestion of less than 4 g. ascorbic acid daily had no significant effect on oxalic acid excretion during the succeeding 24 hr.; 4 g. caused an increase of 12 mg., 8 g. an increase of 45 mg. and 9 g., given for only 2 days, an increase of 68 mg.—W. Godden.

3708

KLEIN, R., PAPADATOS, C. and FORTUNATO, J. **Effect of ascorbic acid on hormonal excretion.** *J. Clin. Endocrinol.*, 1954, **14**, 105-106. [Dept. Paediat., Child. Hosp., Pittsburgh, Pa.]

No significant change was found in the urinary excretion of 17-ketosteroids and 17:21-dihydroxy-20-ketosteroids, when from 1.5 to 5.0 g. ascorbic acid was given daily to 4 normal adults and 4 children. There was in all a sharp decrease in the excretion of "blue chromogens", substances giving the Allen blue colour reaction, which returned to normal after 4 days.—W. Godden.

3709

McSWINEY, R. R., CLAYTON, B. E. and PRUNTY, F. T. G. **Ascorbic-acid metabolism after administration of corticotrophin.** *Lancet*, 1954, **266**, 178-182. [Dept. Chem. Pathol., St. Thomas's Hosp., London.]

Injection of adrenocorticotrophic hormone into patients with initial plasma ascorbic acid values above 0.75 mg. per 100 ml. raised the urinary output of ascorbic acid estimated by the method of Roe and Kuether (Abst. 261, Vol. 13), usually for 2 or 3 days, with evidence of an increase in the amount but not in the proportion of immediate oxidation products. In patients with initial plasma ascorbic acid values below 0.6 mg. per 100 ml. injection of the hormone did not produce these changes. In patients not given the hormone, increase of the ascorbic acid intake raised the excretion of ascorbic acid and its oxidation products in proportions similar to those after the injection.

of adrenocorticotrophic hormone in the first subjects. In guineapigs adequately supplied with ascorbic acid injection of adrenocorticotrophic hormone produced effects similar to those obtained with human subjects with high plasma ascorbic acid values.—W. Godden.

JANDL, J. H. and GABUZDA, G. J. (Jr.) **Potentiation of pteroylglutamic acid by ascorbic acid in anemia of scurvy.** *Proc. Soc. Exp. Biol. Med.*, 1953, **84**, 452-455. [Thorndike Mem. Lab., Second and Fourth Med. Serv., Boston City Hosp., Mass.]

Anaemia associated with scurvy in 2 malnourished men responded to daily intramuscular administration of 125 and 250 μ g. pteroylglutamic acid. When ascorbic acid was given after 10 and 12 days, respectively, a second reticulocyte peak was recorded, the red cell count rose rapidly, and all signs of scurvy disappeared. The first patient excreted no measurable amount of citrovorum factor in the urine, but the second excreted small amounts throughout the period of observation, and increasing amounts of folic acid while pteroylglutamic acid was being given.—A. M. Copping.

3712

FAESSLER, V. **Ergebnisse der Keuchhustenbehandlung mit Vitamin C (Cebion) und Vitamin K (Karanum).** [Treatment of whooping-cough with vitamin C (Cebion) and vitamin K (Karanum).] *Münch. med. Wochenschr.*, 1953, **95**, 1230-1231. [Baisieperstr. 14a, Remscheid, Rheinland.]

Children with whooping-cough were given daily for 6 days intramuscular injections of 10 mg. vitamin K and 250 mg. vitamin C; 4 patients in the catarrhal stage recovered without developing a convulsive cough but, of 15 patients in whom the cough had already reached the stage of whooping, a curative effect was seen only in the 10 treated during the first week of that stage. In 3 contacts, 4 prophylactic injections prevented the occurrence of whooping. The results confirm those reported in the Spanish and South American literature.

Vitamin D

3713

HELLBRÜGGE, T. F. **Die Rachitisprophylaxe durch Vigantolverabreichung in der Neugeborenenperiode und durch Vitamin-D-Zusatz in der**

Säuglingsnahrung. [Prevention of rickets in the newborn with Vigantol and in the infant with addition of vitamin D to the food.] *Münch. med. Wochenschr.*, 1953, **95**, 1323-1327. [Kinderpoliklin., Univ. Munich.]

Florid rickets is almost a thing of the past in Germany, but a mild form is very widespread, which is attributed to the postponement of treatment with vitamin D until the third month of life or later. From 1949 onwards, therefore, newborn infants were given 10 mg. vitamin D₂ on leaving all the lying-in clinics in Munich except 2. In 1952 a survey of babies between 3 and 5 months old given vitamin D was made, comparable with one made in 1948 before treatment of the newborn with vitamin D was begun. The percentage of infants in 1948 and 1952, respectively, was without rickets 18.8 and 25.1, with slight rickets 19.2 and 35.4, with less slight rickets 33.2 and 26.5, with moderately severe rickets 20 and 12, and with severe rickets of 8.8 and 1. Figures in 1952 for babies not given vitamin D from birth did not show any such improvement.

Use of cow's milk, or a milk and cereal infant food, fortified with vitamin D also gave good results.

The results obtained in Munich were, however, never as good as those obtained in Frankfurt where the whole milk supply is irradiated with ultraviolet light. Fortification in one way or another of the whole milk supply with vitamin D is considered to be the most effective method of prophylaxis.—E. M. Hume.

3714

PRENZEL, H. and SIMON, H. A. **Rachitis und vitaminisierte Milch.** [Rickets and vitamin-enriched milk.] *Monatsschr. Kinderheilk.*, 1953, **101**, 397-402. [Elisabeth-Kinderkrankenhaus, Oldenburg.]

The incidence of rickets is still disturbingly high in Germany so, in February and March 1950, a survey was undertaken of all the infants born in Oldenburg between 1 February and 31 December 1949. Craniotabes was the only criterion of which 3 grades were distinguished; only in the lightest grade were there usually no other signs. Of 551 children aged from 8 to 13 months, 45 had rickets of the lightest grade and 7 had rickets of the second or third grade; 456 had had vitamin D as Vigantol. Of 416 babies aged from 2 to 7 months, 163 had rickets of the lightest grade and 96 of the second or third grade; 215 had had Vigantol. When the results were compared with those in other towns, the incidence in Oldenburg was near to that in Cologne, but in both it was only about half that in Bremen or Munich. When the results were analysed according to whether the children had had Vigantol or not, the percentage of those with

N.A. and R., July 1954

rickets, given Vigantol, was in Oldenburg about half that of those not given Vigantol, but in Bremen and Munich the difference was small. The difficulties of prophylaxis are discussed, and it was decided to make an experiment whereby the milk supply of Oldenburg, at no further cost to the customer, was enriched with 1000 "units" of vitamin D₃ per litre, from September 1950. Infants of from 2 to 7 months were examined as before in 1950-51, and the percentage with rickets of the two more severe grades was without Vigantol or enriched milk 20, with Vigantol and without enriched milk 18.3, and with enriched milk and without Vigantol 5.7. The results compared well with those obtained in Frankfurt, where the milk supply is irradiated with ultraviolet light. Such a method of inescapable prophylaxis is preferred. The rather high figure of 1000 "units" vitamin D per litre was chosen to extend protection to infants partly breast fed.—E. M. Hume.

3715

KLINKE, K., BOGNER, W. and GLEISS, J. Zur Dosierung des Vigantol D₃ bei Frühgeborenen. [Dosage of vitamin D₃ for premature infants.] *Deutsch. med. Wochenschr.*, 1954, **79**, 370-371. [Kinderklin., Med. Akad., Düsseldorf.]

On the assumption that vitamin D₃ is more satisfactory for treating babies than vitamin D₂, a change was made from the latter to the former, in the same dosage, in a children's clinic in Nürnberg and another in Düsseldorf, with the result that 2 premature babies in each clinic became very ill. Two of the babies had received 15 mg. vitamin D₃ at the age of 6 weeks, and 2 received 10 mg. three times in the first 9 weeks of life. The intoxication from vitamin D excess was severe, and one of each pair died. The dosage of vitamin D₃ subsequently recommended for premature infants was in Nürnberg 5 mg. given orally, and in Düsseldorf from 60,000 to 120,000 I.U. in oil solution by intramuscular injection at the age of 2 weeks, to be repeated after 4 weeks if necessary.

3716

YAMANOUCHI, T. and MITANI, M. [Studies on rickets. Concerning the serum alkaline phosphatase of rachitic and healthy children. 1.] *Sapporo Med. J.*, 1952, **3**, 61-66. [Dept. Paediat., Sapporo Univ. Med.] In Japanese: English summary.

In the blood serum of rachitic children, values for alkaline phosphatase were high and for inorganic P variable. For diagnosis it is recommended that both should be estimated. After treatment of rickets with a single dose of 15 mg. vitamin D₂, the phosphatase value fell in most of the children, and the inorganic P value rose. Both were higher in healthy children than in healthy adults. There

was no difference between the values for breast-fed and artificially fed infants. (From summary.) E. M. Hume.

3717

LAHA, P. N., CHAKRAVARTI, M. G. and SINGH, R. Serum calcium and phosphorus, 24 hours after massive calciferol therapy. *Indian Med. Gaz.*, 1953, **88**, 508-509. [Dept. Med., Med. Coll., Agra.]

In 6 of 10 men, 24 hr. after intramuscular injection of 15 mg. calciferol, serum Ca was significantly reduced and serum inorganic P was significantly raised; one showed a marked fall in serum P. Other changes were not significant.—F. C. Aitken.

3718

PINCUS, J. B., GITTLEMAN, I. F., SOBEL, A. E. and SCHMERZLER, E. Effects of vitamin D on the serum calcium and phosphorus levels in infants during the first week of life. *Pediatrics*, 1954, **13**, 178-185. [Dept. Paediat., Jewish Hosp., Brooklyn, N.Y.] Spanish summary.

Ca and P were estimated in the blood serum of 5 groups of from 13 to 52 infants on the first day of life and 5 days later. Two groups were given breast milk, one with a daily supplement of 600 U.S.P.U. vitamin D and one without. Three groups received a powdered milk preparation, one without added vitamin D, one with vitamin D incorporated in the milk powder to yield 400 U.S.P.U. per 1000 ml., and one with a separate supplement of 600 U.S.P.U. daily.

In the breast-fed infants there was no significant difference between the mean values on the first and fifth day, though in those given vitamin D the mean value for Ca was lower, and that for P was higher, than on the first day.

In the 3 groups given milk powder, the mean values for P were significantly higher on the fifth day than on the first, but the 3 values did not differ significantly from one another. In all 3 groups the mean value for serum Ca was lower on the fifth day than on the first. The difference was small in the group not given vitamin D, and was larger in the groups given vitamin D, being largest in that given the largest amount, where the difference from the values in the other 2 groups given milk powder was statistically significant. The larger the intake of vitamin D in the groups having milk powder, the larger was the proportion of children with serum Ca values below 8 mg. per 100 ml. The reason why administration of vitamin D should tend to depress the serum Ca value is discussed.—E. M. Hume.

DE VRIES, J. A. and HUISMAN, T. H. J. Het effect van een mengsel van natriumcitraat en

citroenzuur bij een geval van floride rachitis. [**Effect of sodium citrate and citric acid in a case of florid rickets.**] *Maandschr. Kinder-geneesk.*, 1953, **21**, 380-386. [Kinderklin., Rijks. Univ., Groningen.] French and English summaries.

A child of 9 months with florid rickets was given daily for 21 days 9.6 g. citric acid as the acid or as Na citrate. The P content of the blood rose from 3.7 mg. per cent. to 4.2, but radiographically there was no sign of healing. When, however, a single oral dose of 300,000 "units" of vitamin D₃ was given, healing was apparent within 20 days. It is suggested that the dose of citrate was too large.—E. M. Hume.

3720

DE WET, I. S. Vitamine-D resistente ragitis. [**Vitamin-D-resistant rickets.**] *S. African Med. J.*, 1954, **28**, 121-126. [Dept. Orthopaed., Pretoria.]

A short review precedes a full account of 2 cases, a girl of 15 and a girl of 5.—E. M. Hume.

3721

COLEMAN, E. N. and FOOTE, J. B. **Craniostenosis with familial vitamin-D-resistant rickets.** *Brit. Med. J.*, 1954, **i**, 561-562. [City Hosp., Nottingham.]

The case of a boy aged 6 years is reported because of the rarity of scaphocephaly, caused by premature closure of the sagittal suture, in association with vitamin-D-resistant rickets. The rickets was of the type with very low values for plasma P. E. M. Hume.

3722

VAN CREVELD, S. and ARONS, P. Nadare ervarigen bij een bijzonder geval van renale osteoporosis met aminoacidurie, behandeld met dihydrotachysterol. [**A peculiar case of renal osteoporosis with amino-aciduria, treated with dihydrotachysterol.**] *Maandschr. Kinder-geneesk.*, 1953, **21**, 294-300. [Kinderklin., Univ. Amsterdam.] French and English summaries.

For a previous report on the same case, see Abst. 5450, Vol. 19; Title 2707, Vol. 20.

In 1949, early in its second year, the child had severe rickets which did not yield to vitamin D₂, 300,000 "units". The failure was at first attributed to excess of vitamin D, but later, treatment with dihydrotachysterol proved successful, and values for serum Ca and P rose and for alkaline phosphatase fell. Attempts to combat rickets with cod liver oil were completely unsuccessful; the blood values deteriorated and amino-aciduria was present. Recourse to dihydrotachysterol and Ca gluconate was again successful, and the child

has been satisfactorily maintained by that means to the age of 6. The lesion is thought to be one in the kidney tubules.—E. M. Hume.

3723

HOLT, J. F., LATOURETTE, H. B. and WATSON, E. H. **Physiological bowing of the legs in young children.** *J. Amer. Med. Assoc.*, 1954, **154**, 390-394. [Dept. Radiol., Univ. Michigan, Ann Arbor.]

All children with bow legs have not had rickets. Case histories are given for 5 bow-legged children, 3 of them from one family, originally studied at ages of from 6 to 18 months, and representative of 14 at first believed to have rickets or Blount's *osteochondrosis deformans tibiae*. Health and growth were otherwise normal and all but one of the 5 had had regular vitamin supplements from an early age. X-ray photographs showed flaring of the femoral and tibial metaphyses, wedging of the distal femoral epiphyses and other changes, interpreted as structural changes secondary to the bowing, but no sign of rickets at the epiphyseal-metaphyseal junctions. By the time the children had reached ages of from 3 to 5 years the bowing had spontaneously regressed and in some completely disappeared. X-ray examination to rule out rickets is considered essential, but the results must be interpreted with caution.—W. M. Deans.

3724

THOMASCHECK, G. Über die Verhinderung des medikamentös bedingten Haarausfalles durch Vitamin D₂ in Milch-Eiweissbindung. [**Prevention by vitamin D₂ in combination with milk protein of hair loss caused by drugs.**] *Deutsch. med. Wochenschr.*, 1954, **79**, 41-45. [Städt. Frauenklin., Berlin-Neukölln.]

It was noticed that treatment with heparin, even in the smallest effective dose, caused loss of hair, usually from the head, and sometimes total. After a couple of weeks new growth began.

Seven weeks after the beginning of treatment with heparin, 214 women patients were given for 14 days 2 or 3 daily doses of vitamin D₂ in combination with milk protein (Chemische Werke Albert, Wiesbaden-Biebrich), amounting in all to from 180 to 200 mg. A method was devised for grading roughly the extent of the loss of hair, which was much less when the vitamin D preparation was given. It is suggested that the effect is connected with P metabolism.—E. M. Hume.

WALKER, C. H. M. and BALF, C. L. **Capillary resistance studies. 1. The newborn infant. 2. Late pregnancy, labour and early puerperium.** *J. Obstet. Gynaecol. Brit. Empire*, 1954, **61**, 1-16; 17-30. [Dept. Child Life and Health, Univ. Edinburgh.]

1. The "critical petechial pressure" is defined as the pressure producing 1 or more petechiae in 60 sec., provided that a negative test was obtained with a pressure lower by 50 mm. Hg. It decreased with the size of the cup used. Bruising or oedema or both increased as the number of petechiae increased. The number of petechiae rose if the infant cried or struggled. No diurnal change in fragility was found. Except where stated the infants studied were mature and free from infection or abnormality at the first testing. The 622 tests made during a year were grouped into those performed during the first 24 hr. of life, on the 2nd to 4th days inclusive, and on the 5th day or later, and the results were classified into those positive at a pressure of 100 mm. Hg or less and those positive at 150 mm. Hg or more. No seasonal trend was shown.

A study of fatal or non-fatal haemorrhage in foetuses and the newborn showed that there was a seasonal trend in the incidence of stillbirths with subarachnoid and intraventricular haemorrhage but in no other group; such cases formed only 9 per cent. of the 665 studied.

During the first week of life, the younger the infant the greater the fragility of the capillaries; the correlation was statistically significant. A similar trend was present in 34 premature infants examined, and their initial values showed a significantly greater fragility than those of full-term infants; bruising and discolouration of the skin were more frequent in the premature babies and were considered as evidence that the capillaries had not developed fully. Capillary resistance increased significantly with increasing birthweight. No significant difference was found between the capillary resistance of infants of mothers who had received vitamin P prophylactically and of mothers who had not. The administration of vitamin K

to the infant had no appreciable effect on resistance during the first week of life. Peripheral cyanosis had no significant effect. Sex, mode of delivery, and presence or absence of jaundice had no apparent effect, and capillary resistance in the newborn appeared to depend chiefly on the maturity of the capillary bed at birth. The possible influence is discussed of such substances as oestrogens and histamine.

2. Antenatal tests were performed between 2 and 4 p.m. and postnatal tests between 10 a.m. and 12 noon. The mothers were between 20 and 30 years of age. Nurses of the same age served as controls and, as the sample was large, the menstrual state was ignored. Vitamin P had no significant effect on the capillary resistance of pregnant women before, during or after delivery, and the results for treated and untreated women are considered together. The results were divided into those positive at or below a pressure of 150 mm. Hg and those positive at 200 and at or above 250 mm. Hg; the test period was 60 sec., not 30 sec. as used by other workers, so that the critical pressure was lower. The mean capillary resistance during the 6 weeks before term was significantly low. During labour, capillary resistance rose and remained high for the 8 to 10 subsequent days during which the women were retested; the mean final resistance value was significantly above that in the normal control group. In 12 patients with minor complications the values did not differ from those of normal subjects. There was no evidence of any relationship between capillary resistance and the duration of red lochia or the blood loss at delivery, and such obstetrical interference as occurred in the series had no appreciable effect except that in the one subject delivered by caesarean section there was no increase in resistance after delivery. The duration of labour also seemed to have no effect on resistance. There was no close relationship between the capillary resistance of the infant and that of its mother.—L. Wills.

3727

SCHNEEGANS, E. and HAARSCHER, A. **Le complexe vitaminique T. Un nouveau facteur de croissance. [The vitamin T complex. A new growth factor.]** *Pédiatrie*, 1953, **8**, 803-815. [Inst. Puéricult., Strasbourg.] English summary.

Twenty-four infants aged from 4 to 16 months, all of them underweight and not gaining satisfactorily, were maintained on an unchanged diet and treated with 25 drops T Vitamin Goetsch (Pharmazell, Raubling, Bavaria) 3 times a day. Thirteen made a good weight response and some had a much improved appetite. There was no intolerance of the preparation.—E. M. Hume.

DENTAL DISEASES

3728

TURNER, N. C., SCRIBNER, J. H. and BELL, J. T. **The relationship of titratable acidity, titratable alkalinity, and pH to the incidence of dental caries.** *J. Dent. Res.*, 1954, **33**, 55-61. [Lab. Biochem., Forsyth Dent. Infirmary Child., Boston, Mass.]

Saliva was collected from 315 children aged from 5 to 11 years who attended for dental treatment. Frequency distributions and summary tables for the statistical treatment of the data are presented. There was evidence that low titratable acidity and high titratable alkalinity characterised patients free from dental decay, and high acidity and low alkalinity were found in those with greater amounts of dental caries.

D. Harvey.

3729

CARR, L. M. **A correlation between Mellanby hypoplasia and dental caries.** *Dent. J. Austral.*, 1953, **25**, 158-160. [Dent. Clin., Dept. Health, Canberra.]

When the enamel of the teeth of 170 children aged from 3 to 4 years was graded in 4 degrees of roughness, an association between caries and roughness was found.—W. M. Deans.

3730

LILIENTHAL, B., GOLDSWORTHY, N. E., SULLIVAN, H. R. and CAMERON, D. A. **The biology of the children of Hopewood House, Bowral, New South Wales. 1. Observations on dental caries extending over five years (1947 to 1952).** *Dent. J. Austral.*, 1953, **25**, 163-168; repr. from *Med. J. Austral.*, 1953, i. [Inst. Dent. Res., United Dent. Hosp., Sydney.]

The diet in Hopewood House was not analysed but consisted mainly of wholemeal bread and biscuits, wholemeal porridge, wheat germ, fresh and dried fruits, raw and cooked vegetables, butter, cheese, eggs, milk and fruit juices, with vitamin concentrates, honey or molasses occasionally for sweetening, and nuts. Sugar, brown as well as white, white flour and tea were excluded and very little meat was used; food was as far as possible uncooked.

Of 81 children of both sexes aged between 4 and 9 years who had spent most of their lives in the home, 63 had no caries on X-ray examination and in the remaining 18 the incidence and rate of development were low. In respect of caries these children far surpassed Sydney children of the same age (Cameron, 1953, in the press) and were superior even to children in New Guinea villages (Abst. 4246, Vol. 20). Lactobacillus counts were generally low and 30 of the children had no lactobacilli

at any time. There was a significant association between caries and the presence of lactobacilli.

W. M. Deans.

3731

PARFITT, G. J. **Report on the condition of the teeth of children in a London school from 1950 to 1953.** *Brit. Dent. J.*, 1954, **96**, 33-35. [Dept. Prev. Dent., Inst. Dent. Surg.]

Between 1950 and 1952 the mean DMF rate increased and the percentage of children without caries decreased in all age groups between 5 and 10 years; in 1953, however, the 5- and 6-year-olds improved in both respects, but not back to the 1950 values.—W. M. Deans.

3732

SELANDER, P. and GRAHNÉN, H. **Rakiten och spasmodiens inverkan på det permanenta bettet. 1. Tandförändringar. [The effect of rickets and spasmophilia on the permanent occlusion. 1. Changes in the teeth.]** *Nord. Med.*, 1954, **51**, 197-203. [Flensburg, Barnsjukhus., Malmö.] English summary.

Literature is reviewed. From the records of the hospital between 1924 and 1941 three groups of subjects were chosen, 201 that had been admitted in infancy with rickets, 127 with spasmophilia and 173 that, on routine inspection, had neither rickets nor spasmophilia. Of these 62, 56 and 64 were traced and re-examined. In the rickets group 26, average age 18.7 years, showed hypoplasia of the enamel, symmetrical in 17; in the spasmophilia group, average age 17.4, there were 46 with hypoplasia, symmetrical in 41; in the control group, average age 15.6, there were 17 with hypoplasia, symmetrical in only 2. Symmetrical defects are considered to represent lesions during early calcification and referable to the diseases in question. There was no detectable difference in kind or severity of the defects between the groups; the defects were confined to incisors, canines and 6th year molars. There was no evidence of special susceptibility to caries.

I. Leitch.

3733

CARR, L. M. **Some considerations prior to experimental fluoridation.** *Dent. J. Austral.*, 1953, **25**, 208-211. [Dent. Clin., Dept. Health, Canberra.]

The problems which require consideration before fluoridation of a water supply is undertaken are considered under 5 headings: (1) the level at which it is to be made, bearing in mind the quantity of water likely to be consumed under prevailing climatic conditions, (2) the intake of F from water and other sources, (3) the population's caries rate, for the measurement of which the DMF-surfaces index is considered best, (4) the incidence of mottling from causes other than F

N.A. and R., July 1954

intake and (5) the education of the population in what may or may not be expected if fluoridation is undertaken, *e.g.*, immediate inhibition of caries, appearance of toxic effects and interference with industrial processes.—D. Harvey.

3734

ADLER, P. Karies und Urbanisation. [**Caries and urbanisation.**] *Acta med. hung.*, 1954, **5**, 149–168. [Stomatol. Klin., Univ. Debrecen, Hungary.] Russian summary.

Studies made in 1950, 1951 and 1952 of native schoolchildren in 10 large villages or small towns in the Hungarian plain and in the surrounding country showed that the incidence of caries, expressed as the DMF rate, was less in the country children, except in 2 districts where the village children's drinking water contained more F or some other protective substance (see Abst. 1153, Vol. 24). In districts where both groups of children had water of similar F content, the difference was greater in the 12- to 14-year-olds than in the 8- to 9-year-olds, indicating that it is due to some condition affecting the teeth after eruption. Exactly what element in this very slight degree of urbanisation is responsible is not clear. Reliable information on diet was lacking, but little difference seemed likely except that the peasants' children ate more raw vegetables and unripe fruit and had less chance of getting sweets and ice-cream. During the warm half of the year the peasants' children are in the open most of the time, those under school age scantily clad, so that they get more sunshine than the village children.

The increase in caries incidence is no argument against increasing urbanisation, since it can, and should, be combated by fluoridation of the water supplies where necessary.—W. M. Deans.

POISONS: PATHOGENIC ORGANISMS: FOOD LAWS

3736

HÖGL, O. Vergleichende Betrachtung der Schädlichkeit von Lebensmittelkomponenten. [**Comparative study of the toxicity of components of foods.**] *Mitt. Geb. Lebensmittel. Hyg.*, 1953, **44**, 484–494. [Eidg. Gesundheitsamt, Berne.] French and English summaries.

In considering the possible toxicity of a component naturally present or admixed in a food it is suggested that the "safety margin" value should be the criterion. This is expressed as the

ratio of the maximum amount of the constituent, just below the toxic dose, which can be ingested safely, and the amount normally ingested with the food. A ratio of 3.3:1 is somewhat narrow in view of possible cumulative effects, but in a number of cases quoted the ratio is 100:1 or higher.

CALLOWAY, N. O. and MOWREY, F. H. Red blood cells as source of protein for parenteral use. *J. Amer. Med. Assoc.*, 1953, **152**, 777-781. [Med. Serv., Percy Jones Army Hosp., Battle Creek, Mich.]

Since 300 ml. of packed red cells contain 90 g. protein as Hb, they form a much more concentrated source of protein than the usual amino-acid

3744

GLASER, J. and JOHNSTONE, D. E. Prophylaxis of allergic disease in the newborn. *J. Amer. Med. Assoc.*, 1953, **153**, 620-622. [Dept. Paediat., Sch. Med., Univ. Rochester, N.Y.]

Since food sensitivities are much commoner in the first few months of life than later and it is believed that this is due to immaturity of immunological safeguards, cow's milk was withheld from 96 infants, offspring or siblings of persons with allergic disease, for several weeks or months after birth; 88 were given soya bean milk mixtures, 5 meat base mixtures, and 3 were entirely breast fed. Lactating mothers were forbidden eggs and cheese and limited to 1 pint boiled milk daily. Ca and P were supplied by medication. There was a control group of 65 siblings and another group of 175 non-related controls from allergic families. During follow-up periods ranging from 7 months to 10 years, 14 (15 per cent.) of the experimental group, 42 (65 per cent.) of the sibling control group and 91 (52 per cent.) of the non-related control group developed major allergy; the difference was significant.—W. M. Deans.

or protein solutions for parenteral use; and large amounts are discarded by blood banks.

In 8 patients with liver cirrhosis or the nephrotic syndrome, for 4 of whom case histories are given, repeated transfusions with 250 ml. packed red cells improved not only Hb values and red cell counts but also clinical condition and serum protein values. N balance data suggested that the red cells were utilised as a source of protein. No ill effect was seen.—W. M. Deans.

MINDRUM, G. M. **The use of fat supplements in the nutrition of critically ill patients.** *J. Clin. Nutr.*, 1953, **1**, 503-512. [Dept. Int. Med., Med. Sch., Univ. Cincinnati, Ohio.] Spanish summary.

Nine critically ill, protein-depleted patients were given fat emulsions by mouth or stomach tube as supplement to the hospital diet. A typical emulsion consisted of 50 per cent. oil, 12 per cent. sucrose, 2 per cent. emulsifying agent, flavouring and water. Such a mixture supplied 5.1 Cal. per ml. To 100 ml. of this mixture 23 g. skimmed milk powder could be added with little change in volume. The average energy intake from hospital diet was less than 2000 Cal. This was increased to over 4000 Cal. daily by the supplement. During observation periods of from 30 to 120 days patients showed clear improvement, weight gain, increased resistance to infection, accelerated rate of wound healing and a sense of wellbeing.—F. C. Aitken.

3753

GOLDBERG, E. M., STEIN, I. F. (Jr.) and MEYER, K. A. **Administration of fat emulsion by mouth, gastrotomy, and jejunostomy.** *J. Amer. Med. Assoc.*, 1952, **150**, 1665-1667. [Dept. Surg., Northwestern Univ. Med. Sch., Chicago, Ill.]

A 40 per cent. emulsion of groundnut oil was used in the feeding of 90 patients, who, because of lesions of the mouth, oesophagus or stomach, were unable to take sufficient food and were undernourished. Details of the regime are given. The emulsion was given either as a supplement to a fluid or light diet or, if swallowing was impossible, as the basis of a complete diet, in which case it was supplemented with a protein concentrate, minerals and vitamins. The average daily intake was 764 ml. by mouth or about 650 ml. by tube. About half of the patients developed signs of intolerance, but these were generally not severe enough to necessitate stopping the emulsion. There was gain of weight and improvement in the

general condition of most patients except those with advanced malignant disease.—L. Wills.

3754

MOORE, F. D. **The low sodium syndromes of surgery: an outline for practical management.** *J. Amer. Med. Assoc.*, 1954, **154**, 379-384. [Dept. Surg., Peter Bent Brigham Hosp., Harvard Med. Sch., Boston, Mass.]

The 3 basic types of low-serum Na seen in patients after surgical treatment are described: (1) the sodium paradox, where there is normal body Na and body water with low serum Na; (2) water intoxication, where there is normal body Na but too much water with low serum Na; (3) Na deficiency, where there is low body Na with low or normal body water. Usually in Na deficiency the extrarenal loss is high and urine Na is low; relatively rarely the opposite is found with adrenal or renal tubular failure.

With such a diversity of syndromes treatment ranges from careful nursing only to prompt administration of 3000 m. equiv. Na or administration of 9 mg. deoxycorticosterone acetate. Great importance is attached to careful observation and diagnosis.—F. C. Aitken.

DIABETES

3757

ROCHA, A. **Contraindicación de regímenes glucoprivos en ciertos diabéticos. [Contraindication of diets low in carbohydrate for certain diabetics.]** *Rev. española Enferm. Apar. digest. Nutricion*, 1953, **12**, 581-584. [Hosp. Santa Cruz. y San. Pablo, Barcelona.] French and English summaries.

The use of diets excessively low in carbohydrate is contraindicated in diabetes with concomitant hepatitis. Severe deprivation of carbohydrate would diminish the functional capacity of the liver cell, and this would eventually have a harmful effect on the evolution of the diabetes. Maintaining the carbohydrate intake does not call for

insulin medication, since that would tend to deplete the liver of the glycogen so necessary for the unhealthy liver cell. Hence the dietary regimen cannot be the same for all diabetics, but must be modified for each particular case. Estimation of serum cholinesterase will help in the differentiation; its value is normal, or even high, in pure pancreatic insufficiency, but low in diabetic hepatitis, which is commoner than is generally supposed.—M. B. Richards.

WHITE, P., KOSHY, P. and DUCKERS, J. **The management of pregnancy complicating diabetes and of children of diabetic mothers.** *Med. Clin. N. Amer.*, 1953, **37**, 1481–1496. [Joslin Clin., Boston, Mass.]

A useful review based on the unrivalled experience of the Joslin Clinic since 1936, and including data on the growth and other characteristics of the children of diabetic mothers.—A. M. Thomson.

3760

CARDELL, B. S. **The infants of diabetic mothers: a morphological study.** *J. Obstet. Gynaecol. Brit. Empire*, 1953, **60**, 834–853. [Dept. Morbid Anat., King's Coll. Hosp. Med. Sch., London.]

Post-mortem examinations were made of 25 infants of gestational age from 30 to 37 weeks, all but one stillborn or dying within 24 hr., whose mothers were diabetic, and of 64 infants of normal mothers; also of 21 fetuses of gestational age from 14 to 26 weeks, of which 5 were from diabetic mothers. Body length, bodyweight and organ weights are plotted against gestational age.

The infants of diabetic mothers were longer and heavier and had heavier organs than infants of normal mothers. The increases in length and organ weights were related to the increase in bodyweight, except that the brain tended to be lighter, and in 4 the heart was significantly enlarged. The fetuses did not show the increase in bodyweight. Bone structure and ossification were normal. In 13 of 18 infants the pancreas showed an increase of islet tissue, due to an increase of beta cells and closely correlated with bodyweight (Cardell, *J. Pathol. Bacteriol.*, 1953, **66**, 335).

The reasons for the high mortality and abnormalities in the infants of diabetic mothers remain unknown. Overactivity of the anterior pituitary of the mother has been suggested; the author

considers this theory "attractive but not yet supported by adequate evidence", and suggests that heredity may also play a part. Further investigation is called for.—W. M. Deans.

DANOPOULOS, E. and ANGELOPOULOS, B. Vergleichende Untersuchung über die Veränderung des Diabetes in dem Vorkriegs-, Kriegs- und Nachkriegsjahren in Griechenland. [**Comparison of changes in diabetes in Greece in the periods before, during and after the war.**] *Klin. Wochenschr.*, 1953, **31**, 1076–1077. [I. Med. Klin., Univ. Athens.]

It has generally been observed that the incidence of diabetes declines in times of food shortage. In Greece during the war, food conditions were bad, especially in the winter of 1941–42. In the Athens University Clinic, the number of cases of diabetes treated in the year was in the years 1936–40 between 32 and 50 for a total of 1500 to 2500 patients, but in the years 1941–44 it was only from 5 to 7 though the total number of patients seen was no less than before the war. After the war the numbers rose again to the pre-war level and included a larger proportion than before the war of severe diabetes, difficult to stabilise. The improvement during the war is attributed to consumption of a diet largely vegetarian. Tests of the suggestion are being made.—E. M. Hume.

3763

ROSECAN, M. and DAUGHADAY, W. H. **A comparison of insulin treatment with and without added carbohydrate in human diabetic ketosis.** *J. Clin. Invest.*, 1954, **33**, 49–56. [Dept. Int. Med., Sch. Med., Washington Univ., St. Louis, Mo.]

For the comparison, ketosis was induced 20 times in 8 diabetic patients. Blood ketones fell more rapidly when insulin treatment was combined with intravenous administration of fructose or glucose. The period of high blood sugar was shorter and glycosuria was less after fructose than after glucose as an adjunct to insulin treatment.

3764

DARRAGH, J. H., WOMERSLEY, R. A. and MERONEY, W. H. **Fructose in the treatment of diabetic ketosis.** *J. Clin. Invest.*, 1953, **32**, 1214–1221.

N.A. and R., July 1954

[Dept. Int. Med., Sch. Med., Yale Univ., New Haven, Conn.]

Fructose injected intravenously disappeared from the blood of subjects with diabetic ketosis, whether receiving insulin or not, at the same rate as in normal subjects. Only small amounts of fructose were excreted in the urine. If fructose is used in place of glucose, with adequate amounts of insulin, carbohydrate can be administered early in the course of treatment of diabetic ketosis, without increasing the effective osmotic pressure of the extracellular fluid. When 2.5 per cent. fructose in 0.45 per cent. saline was infused the dehydration associated with diabetic ketosis was corrected by the achievement of a large positive balance of water, Na and chloride.—W. Godden.

GASTRO-INTESTINAL CONDITIONS

3768

CORREA, F. W. **Dehydration in children.** *Indian J. Pediat.*, 1954, **21**, 1-15. [Dept. Paediat., Med. Coll., Calcutta.]

Haematocrit value, total chloride in blood and urine and, in some, plasma CO₂-combining power are tabulated for 30 infants and children between 4 and 42 months old with dehydration due to diarrhoea with or without vomiting. All were underweight and anaemic and many had signs of vitamin A or vitamin B complex deficiency. Four were breast fed, 18 breast fed with cow's milk in addition, 1 had tinned milk and 7 mixed diet.

All were suffering from combined water and electrolyte deficiency. The 13 who died showed high haematocrit value, low plasma CO₂-combining power and low blood and urinary chloride compared with those who recovered. Estimation of plasma CO₂-combining power is recommended as a guide to prognosis and treatment.

Treatment was by intravenous saline with 5 per cent. glucose, followed by fluids by mouth as

soon as possible, and later by diluted skimmed lactic acid milk. It is suggested that better results might be obtained by supplying, after the initial stage, potassium and 1/6 M lactate also, as recommended by Darrow *et al.* (*J. Paediat.*, 1949, **4**, 604).

DOUTHWAITE, A. H. and THORNE, M. G. **Further studies on the reduction of gastric acidity.** *Brit. Med. J.*, 1954, **i**, 183-184. [Guy's Hosp., London.]

In an extension of earlier work (Abst. 983, Vol. 23) 12 patients with chronic peptic ulcer and taking ordinary meals were studied while taking alkaline or dummy tablets. Over periods generally of 2 hr. during which 2 to 8 tablets were eaten the alkaline tablets regularly raised the pH of the stomach contents in comparison with the dummy tablets.

From experience of the use of large numbers of these tablets no ill effect can be foreseen, and sucking them may reduce the tendency to relapse in the symptom-free patient.—D. Harvey.

3773

EVANS, P. R. C. **Value of strict dieting, drugs, and "Robaden" in peptic ulceration.** *Brit. Med. J.*, 1954, **i**, 612-616. [Wrexham Group Hosps.]

Four methods of treatment were compared: (1) strict diet with drugs and strict rest in bed; (2) as in (1) with the addition of Robaden, a proprietary preparation of protein-free extracts of fresh animal stomach and small intestine; (3) post-ulcer diet and 2 hr. up and about daily; (4) as in (3) with the addition of Robaden. The patients allotted in rotation to the treatment groups were 27 with gastric and 87 with duodenal ulcer. The duration of strict diet treatment was 1 month in hospital and 3 weeks at home, after which the post-ulcer diet was allowed. The post-ulcer diet

groups also went home after 1 month in hospital. Patients treated with Robaden were given it for 5 months.

The results of a follow-up study for at least 6 months indicated no advantage of strict dieting and strict rest over post-ulcer diet with less strict rest. Robaden had no beneficial effect.

GONZALEZ GALVAN, J. M. Resultados obtenidos con el extracto total de estómago y duodeno en el tratamiento del ulcus gastroduodenal. [Results obtained in the treatment of gastroduodenal ulcer with a whole extract of stomach and duodenum.] *Rev. española Enferm. Apar. digest. Nutric.*, 1954, **13**, 51-62. [Beneficencia Municipal, Seville.] English summary.

Favourable results were obtained with Robudén, a whole extract of stomach and intestine, in the treatment of 52 patients suffering from gastric or duodenal ulcer. Symptoms such as pain, nausea, acidity and spasms disappeared, as did also haemorrhages. There was a general improvement in the weight and morale of the patient and the improvement in the condition was confirmed by X-ray examination. As a rule patients can be treated without interference with their normal occupations, and without the imposition of extreme diets, but not those who clearly require surgical treatment. Detailed case histories of 8 patients are given.—M. B. Richards.

3775

OLSON, W. H. and NECHELES, H. A study on the use of piromen® for the treatment of duodenal ulcer in man. *Amer. J. Digest. Dis.*, 1953, **20**, 372-380. [Dept. Gastro-intestinal Res., Med. Res. Inst., Michael Reese Hosp., Chicago, Ill.]

On the argument that fever and bacterial toxins inhibit gastric secretion and inhibit movement experiments were made with pyrogens which were found to do both. Piromen, "a pyrogenic polysaccharide of bacterial origin", was found to accelerate healing of skin wounds in rabbits. It was tested on inmates of a penitentiary where the incidence of duodenal ulcer is high. There were 52 men with confirmed ulcer. From these 5 were given a placebo with immediate subjective improvement but no real effect; 14 were given Piromen injections and of these 11 showed healed ulcers without change of acidity after from 21 to 44 days. After leaving hospital 5 had Piromen once a week and continued well; only 2 of the other 9 remained well.

A further group of 11 men were treated without hospitalisation; 8 improved and 7 showed healed ulcers.—I. Leitch.

DUFAULT, F. X. (Jr.) and TOBIAS, G. J. Potentially reversible renal failure following excessive calcium and alkali intake in peptic ulcer therapy. *Amer. J. Med.*, 1954, **16**, 231-236. [New England Centre Hosp., Boston, Mass.]

Renal signs with raised levels of urea and Ca in blood developed in 4 patients who had taken excessive amounts of NaHCO₃ and/or CaCO₃ and up to 3 quarts of milk a day for long periods for the relief of ulcer pain. The differential diagnosis from other types of kidney disease and from high blood Ca due to other causes was based on the finding of ocular calcification, the absence of bony changes, the history of excessive intake of soluble alkali and milk and the return to normal of kidney function after the withdrawal of these from the diet.—L. Wills.

3777

ZOLLINGER, R. M. and ELLISON, E. H. Nutrition after gastric operations. *J. Amer. Med. Assoc.*, 1954, **154**, 811-814. [Dept. Surg., Coll. Med., Ohio State Univ.]

Records of weight gain or loss one to six years after operation were used as an index of nutritional state of 203 unselected ulcer patients subjected to standard surgical procedures. There were 176 patients with duodenal ulcer and 27 with benign gastric ulcer. Subjects were considered in 3 groups. Group 1 contained the patients whose pre-operative weight was ideal or above; group 2 contained those who had realised their ideal weight at some time previous to, but not immediately before, the operation; group 3 contained those who had never attained their ideal weight before operation. Of the duodenal ulcer cases two-thirds of those in group 1 attained ideal weight after operation, regardless of the severity of the surgical procedure; the overall proportion in group 2 was lower and varied indirectly with the severity of the surgical procedure; none of the patients in group 3 attained ideal weight after operation. It is suggested that in duodenal ulcer the surgical procedure should be selected with regard to the weight of the patient in relation to his or her ideal weight.

Of the gastric ulcer patients 22 and 21.4 per cent. of those in groups 1 and 2, respectively, attained ideal weight after operation, but none of those in group 3 did. The danger of malignancy in such patients makes radical resection necessary, regardless of pre-operative weight.—F. C. Aitken.

THYROID DISEASE

3781

BLUM, F. Studien zum Kropfproblem. 5. Kropfaufbau und Kropfarten. Experimentelle Studie. [Studies of the goitre problem. 5. Formation and kinds of goitres. Experimental study.] *Schweiz. med. Wochenschr.*, 1953, 83, 513-518. [Zürich.]

The author expresses certain of his conclusions in a general article and adduces in support of them specimen experiments from among those he has made.

Goitre in rabbits and other animals caused by a diet of cabbage is different from goitre caused by sulphur compounds like thiourea. In cabbage goitre, the dietary I offered to the thyroid gland is in an unavailable form and the gland becomes filled with inactive material. When free I is offered it can be used, and active substance may be formed in amount greater than can be stored in the gland until there has been time for the inactive substance to be removed. An excess of active substance is then left in the circulation and signs like those of Graves' disease appear. This state can be maintained almost indefinitely by suitable dosage with I; the gland is, however, capable of being restored to normal.

In the goitre caused by giving sulphur compounds, even colloidal S, it is an enzyme which is damaged and, if the intoxication lasts long enough, the enzyme is irreparably destroyed and free I offered to the gland cannot be used. In rabbits and rats, goitres were produced by feeding the animals for 3 months with a culture of purple sulphur bacteria. When I was given there was little reaction, showing that the bacteria acted by damaging the enzyme. It is suggested that the intestinal flora of human beings may at times include such goitrogenic organisms.

HASHIBA, T., OGAWA, M. and OTSUKA, R. [Surveys and studies on endemic goiter in Hidaka, Hokkaido.] *Sapporo Med. J.*, 1952, 3, 252-256. [Dept. Surg., Sapporo Univ. Med.] In Japanese: English summary.

Among 4683 schoolchildren aged from 6 to 18 years the incidence of goitre was 3.05 per cent. Distribution was not uniform; goitre was more common in the eastern part of the Erimo peninsula, where 12 per cent. of the children were affected. Investigation of the cause is being continued. (From summary).—D. Harvey.

3783

OKII, K. [Studies on distribution of the endemic goiter in Hokkaido. The investigation in Esashi district.] *Sapporo Med. J.*, 1952, 3, 329-331. [Dept. Surg., Sapporo Univ. Med.] In Japanese: English summary.

In a population of 2234 the incidence of goitre was 2.3 per cent., and the degree of hypertrophy was, in general, greatest in areas where the disease was commonest. (From summary).—D. Harvey.

3784

PERINETTI, H., YACIOFANO, C. A., STANELONI, L. and NORA, J. N. Nuestra experiencia medico quirurgica sobre bocio en una zona endemica. [Recent medico-surgical experience of goitre in an endemic area.] *Rev. Fac. Ciencias méd.* "Dr. Thomas Peron", 1952, 1, No. 3, 7-24. [Inst. Bocio, Univ. Nac. Cuyo.]

Goitre is common in the province of Mendoza in Argentina. A survey of 52,548 schoolchildren in 1940 revealed its presence in 46 per cent. The drinking waters contain little iodine, and the use of iodised salt is recommended.—E. M. Hume.

3785

VAN LEEUWEN, E. Een vorm van genuine hyperthyreose (M. Basedow zonder exophthalmus) na gebruik van geijodeerd brood. [A form of true hyperthyroidism (Graves' disease without exophthalmos) after eating iodised bread.] *Nederland. Tijdschr. Geneesk.*, 1954, 98, 81-89. [Emmen.] English summary.

Goitre prophylaxis in the Netherlands since 1942 has been organised on the basis of the use of iodised salt in baking bread. Up to March 1948 the salt contained 26 mg. KI per kg. and thereafter 39 mg. With bread rationed at 1800 g. weekly the daily extra I from bread was about 100 μ g. When rationing ended and consumption rose to 300 or

400 g. daily, extra I would be approximately 120 to 160 μ g. daily. In August 1948 the baking of bread with iodised salt began in the towns of Emmen and Odoorn. During the 10 preceding years, Graves' disease occurred in classical form in only 9 patients. In 1949 there were 19, in the 3 following years 17, 17 and 5 patients with hyperthyroidism without exophthalmos, in most of them without goitre, and with an age distribution extending into old age. In 1953 no further case appeared. Treatment of those affected, by omission of iodised salt, was not uniformly effective.

I. Leitch.

3786

GALBRAITH, H. J. B., NASH, D. F. E. and SPENCE, A. W. **Iodothiouracil in treatment of toxic goitre.** *Brit. Med. J.*, 1954, i, 420-422. [St. Bartholomew's Hosp., London.]

Of 23 patients treated with 200 or 300 mg. iodothiouracil daily for from 12 days to 7 months, 18 subsequently underwent thyroidectomy. Six others were given simultaneously before operation equivalent doses of thiouracil as methylthiouracil, and of iodine. With such treatment there took place within a week an increase in weight, reduction of the B.M.R. and clinical improvement. It is concluded that either method is satisfactory for pre-operative treatment and preferable to the giving of thiouracil and I separately in preparation for operation.—B. W. Simpson.

3787

GODLEY, A. F. and STANBURY, J. B. **Preliminary experience in the treatment of hyperthyroidism with potassium perchlorate.** *J. Clin. Endocrinol.*, 1954, 14, 70-78. [Dept. Med., Harvard Med. Sch., Boston, Mass.]

A therapeutic trial was made of perchlorate in the treatment of 24 patients with the classic signs of Graves' disease, the dosage being usually 200 to 400 mg. every 8 hr. Some were given iodide in addition to perchlorate before operation and some received perchlorate on a continuing basis. The results were promising. The only toxic sign encountered was irritation of the gastrointestinal tract and it was not certain that the drug was responsible for this. It is suggested that potassium perchlorate may be an effective antithyroid agent in the pre-operative or continuous treatment of thyrotoxicosis, especially in patients where drugs of the thiourea group or iodide have failed or are not tolerated, but the possibility of other reactions must be borne in mind.—B. W. Simpson.

NICCOM, W. L., JACKSON, R. L. and STEARNS, G. **Use of ferric and ferrous iron in the prevention of hypochromic anemia in infants.** *Amer. J. Dis. Child.*, 1953, 86, 553-567. [Dept. Paediat., Coll. Med., State Univ. Iowa.]

Artificially-fed fulltime, premature and immature infants were given in milk 5 mg. Fe daily from 3 to 6 months of age and 10 mg. Fe daily from 6 months of age.

In 37 term infants given ferrous sulphate mean Hb values at 29 and 38 weeks were significantly higher than values of 115 term infants given ferric ammonium citrate. Of the 115 infants 16 had severe infections, but the amounts of ferric Fe given sufficed to maintain Hb values above 10 mg. per 100 ml. Four somewhat premature infants who were given ferrous sulphate were able to maintain Hb values greater than 10 mg. per 100 ml. Of the immature infants studied, a set of twins and a set of triplets, 4 were given blood transfusions to bring Hb values near normal. Thereafter the treatment with Fe as ferric ammonium citrate maintained Hb values above 10 mg.—F. C. Aitken.

3792

ADAMS, E. B. **Anaemia in kwashiorkor.** *Brit. Med. J.*, 1954, i, 537-541. [King Edward VIII Hosp., Durban.]

Twenty-one patients with pitting oedema, dermatosis and low plasma proteins were selected for a study of blood. Ages ranged from 1 to 5 years. The diet treatment was soured milk with or without a hydrolysed protein preparation. Eleven children recovered completely, 3 died and 7 were removed from hospital before recovery was complete.

The lowest Hb levels, often recorded after treatment was beginning to give clinical improvement, were below 9 g. in 14 and below 7 g. in 6

N.A. and R., July 1954

children. Bone marrow was normal in 13. There was megaloblastic change in 2. Six had giant metamyelocytes and some red cell precursors of intermediate type.

The possible relationship of anaemia in kwashiorkor to protein deficiency is discussed.

F. C. Aitken.

3793

DAVIS, L. R. and JENNISON, R. F. **Response of the "physiological anaemia" of pregnancy to iron therapy.** *J. Obstet. Gynaecol. Brit. Empire*, 1954, **61**, 103-108. [King's Coll. Hosp. Med. Sch., London.]

Women numbering 221 and believed to be about 32 weeks pregnant were selected for study; the number was later reduced to 174 by the rejection of those who were considered to have been pregnant for less than 30 or for more than 34 weeks. The mean Hb level of these 174 was 78.14 per cent. (Haldane); the distribution of levels is shown diagrammatically. Before further study 89 more patients were excluded because of irregular attendance at the clinic, confinement at home or initial Hb below 70 or over 88 per cent. The remaining 85 patients were subdivided into 2 groups according as Hb was initially above or below 80 per cent. and in each subgroup approximately half the patients received iron in the form of 2 uncoated tablets of FeSO_4 (B.P.) thrice daily. Significantly raised packed cell volumes and Hb levels at term were found in the treated as compared with the control patients, and among the treated the scatter of levels was narrower. Less consistent changes were found in the mean corpuscular Hb concentrations. Serum Fe was unaffected. It is concluded that the "physiological anaemia" of pregnancy is a result of Fe deficiency.—A. M. Thomson.

3794

CHATTERJEE, J. B. and DAS GUPTA, C. R. **Dimorphic anaemia.** *Indian Med. Gaz.*, 1953, **88**, 126-144. [Dept. Haematol., Sch. Trop. Med., Calcutta.]

Detailed clinical, haematological, biochemical and therapeutic investigations were made of 103 patients with deficiency anaemias, 27 of whom were diagnosed as having dimorphic anaemia. This type of anaemia cannot be diagnosed clinically and the biochemical findings are non-specific. The peripheral blood picture is also non-specific, but the diagnosis is possible from an examination of the bone marrow. Three different pictures may be seen. The presence in a wholly normoblastic marrow of abnormal giant stab cells, metamyelocytes and megakaryocytes is considered diagnostic of deficiency of anti-megaloblastic factors. The diagnosis can be confirmed or, in the absence of a marrow examination, may be made on the results

of treatment, since complete haematological remission is obtained only if both Fe and anti-megaloblastic substances are given.—L. Wills.

HUDSON, F. P., IRELAND, J. T., OCKENDEN, B. G. and WHITE-JONES, R. H. **Diagnosis and treatment of galactosaemia.** *Brit. Med. J.*, 1954, **i**, 242-245. [Alder Hey Child. Hosp., Liverpool.]

Clinical descriptions are given of 4 cases of abnormal metabolism of lactose by infants, of whom 3 died. In 2 of these there was positive evidence of high galactose content of the blood but in the third a presumptive diagnosis of the disease was made from its appearance later in a sibling. The infant which survived was given Nutramigen imported from the United States because no lactose-free infant food is prepared in Britain. The question of consanguinity of the parents has not received sufficient attention to confirm the suggestion that the disease is due to a recessive gene in homozygous form.—D. Harvey.

3798

JOHNSON, J. **Cataracts in galactosemia.** *Amer. J. Ophthalmol.*, 1953, **36**, 1380-1386. [Dept. Ophthalmol., Univ. Texas Med. Branch, Galveston.]

The signs of the disease are described; besides cataract, jaundice and hepatomegaly are prominent. The cases reported in the literature in and after 1945 are tabulated. Three patients, a girl of 3 weeks, a girl of 4 months and a boy of one year,

25

are described. Improvement began at once when milk was replaced by a soya bean preparation. The importance of diagnosis and treatment before the third month of life is stressed; otherwise the opacities in the lens become irreversible.

E. M. Hume.

3799

MCAULEY, F. D. **Cataracts in galactosaemia.** *Brit. J. Ophthalmol.*, 1953, **37**, 655-660. [London.]

The signs of the disease are described. Galactosaemia is reported in 2 boys, 12 days and 4 weeks old. Lactose was excluded from the diet, and the opacities in the lens gradually improved.

E. M. Hume.

3800

DELTHIL, P. L'intolérance au saccharose chez l'enfant. [**Sugar intolerance in children.**] *Presse méd.*, 1953, **61**, 1643-1645. [Paris.]

Skin, digestive and nervous troubles in young artificially fed infants otherwise in good condition and gaining weight regularly may arise from intolerance for sucrose, probably due to insufficient secretion of invertase. The stools may have a high pH and may contain a high proportion of Gram-negative organisms. A conclusive test is to substitute some other sugar, preferably β -lactose added to the feed at the last moment, in amount to give not more than 7 or 8 per cent. lactose in all. As a rule ordinary sugar can be re-introduced gradually at about 3 months of age. In older children the syndrome is generally found only when sugar consumption is excessive, but the signs may be erroneously ascribed to some more valuable food, such as eggs. Treatment with vitamin B complex may be helpful.

For some unknown reason sugar intolerance is more frequent with dried milk containing 7 to 8 per cent. sugar than with sweetened condensed milk containing 10 per cent. It is suggested that manufacturers of dried milk should produce alternative products, either unsweetened or sweetened with a mixture of sugars.—W. M. Deans.

3801

FREUDENBERG, E. Weitere Beobachtungen zur Frage der "Cystinosis". [**Further observations on cystinosis.**] *Ann. paediat.*, 1954, **182**, 85-106. [Kinderspital, Basle.] English and French summaries.

Clinical and laboratory studies of a year-old child with cystinosis, retarded growth, severe rickets, renal glycosuria and amino-aciduria are described. Deposits of tyrosine as well as cystine were detected in the bone marrow. Treatment with alkalis and choline was without effect, but daily intramuscular injections of 50 mg. adenosine phosphate cured the rickets, which had not

responded to correction of the Ca:P ratio of the diet or to vitamin D; the glycosuria disappeared and the amino-aciduria was much reduced.

DEMEULENAERE, L. Stéatose hépatique et antibiotiques. [**Fatty liver and antibiotics.**] *Acta gastro-enterol. belg.*, 1953, **16**, 791-795. *Proc. Clin. Méd., Univ. Ghent.*

Two cases are described in which fatty liver is ascribed to prolonged use of antibiotics.

3806

HALL, E. M., OLSEN, A. Y. and DAVIS, F. E. **Portal cirrhosis. Clinical and pathologic review of 782 cases from 16,600 necropsies.** *Amer. J. Pathol.*, 1953, **29**, 993-1027. [Dept. Pathol., Sch. Med., Univ. S. California, Los Angeles.]

The development of cirrhosis was in 3 phases, the first subacute and characterised by a large fatty liver, the second subchronic with moderate to marked cirrhotic changes and moderate enlargement of the liver and the third chronic and showing characteristically an atrophic hobnail liver. Fibrosis was minimum to moderate in the subacute phase, moderate to advanced in the subchronic and generally advanced in the chronic phase. The spleen was enlarged in 60 per cent. of the cases. The incidence of coronary thrombosis in patients up to the age of 50 was half that in a control group of non-cirrhotic patients, and in the cirrhotic patients the incidence of hypertension was relatively less still. Acute or chronic infection was the commonest cause of death. The hospital

N.A. and R., July 1954

records showed that the percentage of deaths due to cirrhosis was between 4.2 and 5.8 during the period 1941 to 1947. As the case histories were insufficient to indicate the incidence of alcoholism, a separate study was made of 100 cirrhotic patients in the same hospital. It showed that 92 of these patients were heavy drinkers and that wine and whisky were the forms of drink most frequently taken. There was a deficiency of protein in the diets of 45 and of vitamin B complex in the diets of 60 of these 100 patients.—L. Wills.

DUNSTER, M. O., MCGOWAN, G. K. and BENNETT, D. **The effect of cation exchange resins in the treatment of pre-eclamptic toxæmia of pregnancy.** *J. Obstet. Gynaecol. Brit. Empire*, 1954, **61**, 31-45. [Dept. Obstet. Gynaecol., United Bristol Hosps.]

Seven cases of pre-eclampsia were treated with "Resodec", a cross-linked polyacrylic polycarboxyl cation exchange resin of which 77 per cent. is combined with ammonia and 23 per cent. with K, usually in doses of 30 g. thrice daily for 3 days, then with half this dose. The clinical details in each case are described. It is concluded that the treatment, combined with a diet low in Na, is effective in diminishing water retention and is beneficial in permitting continuance of pregnancy in severe cases of pre-eclampsia.—A. M. Thomson.

3809

TENNEY, B. **Hypertension in pregnancy.** *New Engl. J. Med.*, 1953, **249**, 1108-1115. [Dept. Obstet. Gynaecol., Sch. Med., Univ. Boston, Mass.]

The diagnosis and treatment of renal disease, essential hypertension, pre-eclamptic toxæmia and eclampsia are described. The principal feature of diet treatment is restriction of Na intake.

HUTCHINSON, D. L. and PLENTL, A. A. **Investigations on the use of sodium-removing resins in the treatment of pre-eclampsia.** *Amer. J. Obstet. Gynecol.*, 1954, **67**, 32-46. [Dept. Obstet. Gynaecol., Coll. Phys. Surg., Columbia Univ., New York.]

Studies were made on 4 patients with pre-eclampsia, and less systematic trials on 3 others. After preliminary treatment by rest, low-salt diet, mild sedatives and NH_4Cl , they were given "Carbo-Resin" in maximum amounts, usually about 72 g. daily in 3 doses. When urinary Na output and serum CO_2 combining power began to decrease, resin was discontinued. The most consistent result was a fall in urinary Na output from between 40 and 105 to less than 5 m. equiv. daily. Total body water decreased roughly in proportion to bodyweight, but the reduction was exceeded both relatively and absolutely by decline in the Na space. The reduction of body Na was most significant when expressed as m. equiv. per kg. bodyweight. Serum Na and K concentrations remained within normal limits. A significant fall in the CO_2 combining power of serum, with normal serum chlorides and blood pH, occurred at the height of the therapeutic effect of the resin. Plasma volume decreased slightly. The resin had no consistent effect on proteinuria or blood pressure, but they did not increase. In the control of resin therapy, estimation of serum CO_2 combining power was the only laboratory test required.—A. M. Thomson.

3812

LANE, H. S., COLLIN, H. A., DARO, A. F. and NORA, E. (Jr.) **Hypokalemia due to persistent vomiting during pregnancy.** *J. Amer. Med. Assoc.*, 1953, **153**, 1012-1017. [Dept. Surg., Cook County Hosp., Chicago, Ill.]

In 8 cases of severe vomiting of pregnancy accompanied by weight loss, serum K was below 3.4 m. equiv. per litre. Blood chemistry data tabulated include K, Na, Cl, CO_2 combining power, N.P.N. and creatinine. Detailed notes of 3 cases are given. Treatment with parenteral K "resulted in a striking improvement in mental attitude and muscular strength. In several cases, this appeared to be a lifesaving procedure."

A. M. Thomson.

3813

ULICH, K. and WOLF, W. **Über den Kochsalz- und Natriumgehalt der "salzfreien" Krankenkost.** [Sodium chloride and sodium content

of "salt-free" invalid diet.] *Deutsch. med. Wochenschr.*, 1954, **79**, 108-110. [Pharmakol. Inst., Freie Univ. Berlin.]

It is considered that the diet for patients with oedema under treatment with cation exchange resins should not contain more than 800 mg. Na or 2 g. salt daily.

The results of Na estimations by flame photometer in some 50 foods, from manufacturers of special foods and all described as "low-salt" or "salt-free", are tabulated along with the calculated NaCl contents. Sausages and other meat products mostly contained from 0.3 to 0.9 per cent. Na; 2 samples of bread had over 0.4 per cent. and some kinds of cheese and other spreads (but not nut spreads) had over 0.3 per cent. In a few samples Cl was estimated also and the NaCl contents calculated were so low that other salts of Na must have been present. Since in Germany the salt content of foods is almost always computed from estimations of Cl, the results may be highly misleading, and it is contended that firms should be forced to declare the Na content of their products.

Finally, some hints are given on the planning of a diet with some variety and supplying not more than 800 mg. Na. The most important item is salt-free bread. For breakfast the patient can have an egg, with salt-free rolls, unsalted butter, and jam; for the mid-day meal meat, potatoes, vegetables, pudding and fruit; for supper bread, butter, curds, meat, fruit. If the diet is genuinely low in Na, the fluid intake need not be restricted.

MITCHELL, G. W. (Jr.) and ROGERS, J. **The influence of weight reduction on amenorrhea in obese women.** *New Engl. J. Med.*, 1953, **249**, 835-837. [Pratt Diagnostic Clin., New England Centre Hosp., Boston, Mass.]

When 32 obese women with amenorrhoea unaccounted for by pelvic disorder or systemic disease were treated with a 1200-Cal. diet, 13 lost weight and began to menstruate again, 15 did neither, 2 lost weight without return of menstruation and 2 menstruated but did not lose weight. In several, menstruation began before much weight had been lost. It is suggested that decreasing bodyweight rather than absolute loss of bodyweight had a favourable effect, or that some emotional factor was responsible for both the obesity and the amenorrhoea.—W. M. Deans.

SIMPSON, J. A. **Dermatological changes in hypocalcaemia.** *Brit. J. Dermatol.*, 1954, **66**, 1-15. [Gardiner Inst. Med., Univ. Glasgow.]

The skin, nail and hair changes found in 5 patients with hypoparathyroidism are described. In this condition low blood Ca occurs without other sign of deficiency. In 29 patients with steatorrhoea, 2 of whom are described in detail, skin changes similar to those of hypoparathyroidism were seen. Since multiple deficiencies occur in steatorrhoea, the skin changes cannot be definitely attributed to Ca deficiency, although in some serum Ca levels as low as 7.0 mg. per 100 ml. and bone changes indicative of prolonged Ca deficiency were found. From a study of these cases and of others from the literature it is suggested that the dermatological changes associated with low blood Ca are alopecia, with transverse grooving of the nails and oedema due to angiospasm, dry scaly pigmented skin with scanty hair growth, and onychorrhexis and secondary mycotic infections of the nails. The problem of *impetigo herpetiformis* and the possibility of a specific skin lesion in idiopathic hypoparathyroidism are discussed.—M. B. Richards.

Treatment with 50 to 100 ml. daily of a mixture of 140 g. citric acid and 98 g. sodium citrate per litre gave a return towards normal of the alkali reserve, recovery of muscle strength and resumption of growth.—I. Leitch.

3825

MAUTNER, H. **The pathologic anatomy and physiology of mental retardation.** *Ann. paediat.*, 1954, **182**, 76-84. [Wrentham State Sch., Wrentham, Mass.] German and French summaries.

Recent research suggests that not the frontal lobe nor the cortex in particular is the seat of intelligence; the thalamus may be more important. Damaged areas such as occur in epileptics may affect the functioning of other areas.

Mental abnormalities are associated with abnormalities of metabolism. Acetylcholine, the enzymes cholinesterase and choline acetylase, and

adenosinetriphosphate, with glutamic acid, are concerned in mental activity. Lack of oxygen or of carbohydrate retards activity.

Patients with certain types of metabolic abnormality, e.g., phenylpyruvic oligophrenia, show low oxygen consumption, which may be attributed to either failure of development or destruction of respiratory enzymes. Phenylpyruvic oligophrenics lack the power to convert phenylalanine to tyrosine. The presence of an antagonist has been postulated but not proved. Phenylalanine itself may be a poison. Other amino-acids may be involved in disturbances in this, or related, abnormalities.

Several lipid storage diseases produce mental deterioration and ultimately idiocy.

Carbohydrate is the essential fuel. There is no mental disturbance in diabetes, but somnolence or unconsciousness is characteristic of, e.g. adenoma of the pancreas, with low blood sugar. Glycogen storage disease produces mild mental retardation.

The mental changes in cretinism may be due to defective oxidation or may be related to abnormal protein metabolism.—I. Leitch.

- RAYMOND, W. F., HARRIS, C. E. and HARKER, V. G. **Studies on the digestibility of herbage. 1. Technique of measurement of digestibility and some observations on factors affecting the accuracy of digestibility data. 2. Effect of freezing and cold storage of herbage on its digestibility by sheep.** *J. Brit. Grassland Soc.*, 1953, **8**, 301-314; 315-320. [Grassland Res. Stat., Drayton, Stratford on Avon.]

1. The technique of digestibility experiments with sheep grazing outdoors, or fed indoors in metabolism crates with grass stored at 0° F., is described. Faeces collection bags were used in both indoor and outdoor experiments. Methods of analysis for dry matter, N, "crude fibre" and "chromogen" on a cream of wet faeces are discussed. Studies of the optimum length of the collection period and the number of sheep required to detect differences in digestibility were made.

2. Experiments to test whether herbage given after cold storage at 0° F. had the same digestibility as it would have had if fresh are described.

There was no significant effect of freezing on the digestibility of organic matter, dry matter or N. An apparent difference was explained by a change in the digestive abilities of the sheep over the 50-day experimental period.—D. M. Walker.

3835

- MILLER, W. J., WAUGH, R. K. and MATRONE, G. **Comparison of the digestibility of certain pasture forages in the fresh and dried states.** *J. Animal Sci.*, 1954, **13**, 283-288. [Dept. Animal Indust., N. Carolina Agric. Exp. Stat., Raleigh.]

The digestibility by rabbits of lignin and of the proximate nutrients in ladino clover, tall fescue and orchard grass was estimated with fresh and dried material. Drying at 55° to 60° C. depressed the digestibility of protein and lignin in all 3 species. The digestibility of crude fibre and of N-free extract in the clover was depressed by drying, but in the grasses the digestibility of these nutrients was higher in the dried material than in the fresh forage. The digestibility of all proximate nutrients and of lignin was higher in the clover than in the grasses. The lignin in the fresh ladino clover was digested to 26.4 per cent. compared with 6.0 and 9.1 per cent. for tall fescue and orchard grass, respectively.—D. M. Walker.

3836

- DHARMANI, L. C. and KARIRA, G. V. **Maize cake as a cattle feed.** *Indian J. Vet. Sci.*, 1953, **23**, 123-127. [Dept. Agric. Punjab, Ludhiana.]

The digestibility of maize cake made from maize bran and molasses in the Punjab was estimated with 6 Sahiwal heifers. The results were compared with those for cottonseed cake, *sarson* cake and *toria* cake. Chemical analysis showed the maize cake to be richer in fat (19.8 per cent.) and N-free extract (43.1 per cent.) and poorer in protein (19.5 per cent.) than the other cakes. The fat was slightly more and the protein slightly less digestible than that of *sarson* or *toria* cake. Giving green berseem with the maize cake to make it more acceptable to the cattle improved the digestibility of fat from 87 to 98 per cent. and of protein from 64 to 70 per cent., but had little effect on the digestibility of the dry matter or N-free extract. There was no ill effect from the high fat content of the maize cake. The suitability of the cake for storage is being investigated.—T. D. Bell.

3837

- DAVIDSON, W. M. and KENNEDY, J. W. **Digestibility studies with swine. 7. Gross energy values and ether extract determinations.** *Canad. J. Agric. Sci.*, 1953, **33**, 611-614. [Div. Chem., Sci. Serv., Dept. Agric., Ottawa.]

In previous work with pigs Watson *et al.* (Abst.

N.A. and R., July 1954

5977, Vol. 20) found that the inclusion of 30 per cent. tankage in a barley ration raised the apparent digestibility of the ether extract contributed by barley from 58 to 90 per cent. In further trials with 6 similar pigs in which the digestibility of 2 vegetable protein and 3 animal protein supplements in a barley ration was estimated, it was shown that the gross digestible energy values calculated from the composition of food and faeces depended on the method used for the estimation of fat in the food and faeces. Gross digestible energy values, particularly for tankage and meatmeal, obtained by calculation, using the results for fat obtained by the acid hydrolysis method of Wood and Simpson (Abst. 3134, Vol. 4), were in much closer agreement with those obtained by the bomb calorimeter than were those obtained with the results for fat from straight extraction with light petroleum. The difference in values obtained by the two methods for faecal fat is partly correlated with the Ca content of the faeces, but this is not the sole cause.—W. Godden.

3838

BRUNE, H. Fehlernährung mit Rübenblattsilage und Troblako. Experimenteller Rübenblatt-durchfall beim Hammel unter Berücksichtigung von Adsorbentienbeifütterung. 1. Die organische Substanz des Futters. [Unsuccessful use of beet leaf silage and Troblako. Experimental diarrhoea due to beet leaves in wethers with reference to the simultaneous feeding of adsorbents. 1. The organic matter of the ration.] *Arch. Tierernährung*, 1953, 3, 281–312. [Inst. Tierphysiol., Univ. Göttingen.]

Digestibility trials over a period of 2 years were made with 4 sheep in which beet leaf silage or Troblako was given alone or with the addition of 150 g. oat straw, 45 or 100 g. heavy kaolin (*bolus alba*), 50 g. activated charcoal, 56.5 g. cellulose, 30 g. chalk, 2 or 4 g. cholesterol or 4 g. of a crude ether extract of hay.

The single beet leaf products, without supplements, led to "beet leaf diarrhoea". Changes were noted in the percentage dry matter in the faeces which were related to some extent to the supplements and to the duration of the experimental period. *Bolus alba* caused a change in the physical condition of the faeces and 100 g. daily reduced the digestibility of the organic matter of the ration. The amount of carotene in the faeces decreased when *bolus alba* or CaCO_3 was given as a supplement to Troblako (cf. Abst. 2838, Vol. 23). The addition of 2 or 4 g. cholesterol daily to either of the single feeds raised the percentage dry matter in the faeces. Crude ether extract from hay, 4 g. daily, exercised a regulatory effect on the physical state of the faeces. Prolonged feeding of either beet leaf product caused a drop in serum

cholesterol, which quickly rose again when cholesterol was given as a supplement. The amount of unsaponifiable matter in the faecal fat changed with the percentage solids in the faeces as affected by the cholesterol supplement. The percentage of oxalic acid in the feed excreted in the faeces decreased after about 20 days on beet leaf to about 75 per cent. and remained fairly constant regardless of the supplement given. The Ca balances were in general negative throughout the experimental period. The N balances were positive except on 3 occasions.—W. Godden.

3839

DIJKSTRA, N. D. De verteerbaarheid en voederwaarde van bieten. [The digestibility and feed value of fodder beet.] *Versl. Landbouwk. Onderzoek.*, 1953, No. 59.7, pp. 16. [Rijkslandbouwproefstat., Hoorn.] English summary.

Earlier data are summarised. Four varieties of beet, two of them grown on different soils, were tested in experiments with 3 wethers given 200 g. dried grass or hay of high quality and amounts of beet equivalent in terms of dry matter (DM). In the 6 samples tested DM rose from 11.5 to 23.0 per cent. and as a percentage of DM, crude protein fell from 7.6 to 5.7, true protein from 3.6 to 3.1 and crude fibre from 7.0 to 5.5. Digestibility varied little. The coefficients were for DM 87 to 90, organic matter 90 to 93, carbohydrates (other than fibre) 95, fibre on the average 83.5, amides 95, but true protein only 12 to 34. Digestibility of crude protein increased with percentage crude protein in DM. Kellner's value of 72 is used to compute starch equivalent, which differed little from 60 in DM and increased from about 7 to 14 in fresh roots as DM rose.—I. Leitch.

3840

GALLUP, W. D., POPE, L. S. and WHITEHAIR, C. K. Urea as a source of protein in livestock rations. *Oklahoma Agric. Exp. Stat. Circ.* No. C-137, October 1953, pp. 10. [Oklahoma Agric. and Mech. Coll., Stillwater.]

The use of urea as a protein extender in livestock rations is discussed. The results of feeding trials are summarised.

With fattening calves, full-fed on grain, pelleted protein supplements in which urea supplied the equivalent of 25 or 50 per cent. of the protein were as good as plant protein supplements. When urea supplied the equivalent of 85 per cent. of the protein results were unsatisfactory. A 25 per cent. urea pellet was a satisfactory supplement to dried grass for wintering yearling heifers, 2-year-old steers and mature beef cows.

Metabolism trials with sheep showed that they could utilise urea nitrogen as a substitute for

protein, but in fattening rations for lambs urea could not replace the protein. Urea could replace one-third of the protein in rations for pregnant and lactating ewes without detrimental effect on gains, fleece weight or weight of lambs.

Low-protein roughages were not satisfactorily supplemented unless a carbohydrate concentrate was also included.

Ca, P and vitamin A metabolism of sheep was not affected by the feeding of urea. Small amounts of methionine increased the value of urea in sheep rations.

(The experiments are summarised from *Oklahoma Agric. Exp. Stat. Bull.* No. B-409.)—T. D. Bell.

KROSBY, P. and ULVESLI, O. Et forsøk til belysning av fôrmargkalens verdi. [**Feeding value of marrowstem kale.**] *Tidsskr. norske Landbruk*, 1953, **60**, 335–346. [Statens Frøkontroll, Ås.] English summary.

Marrowstem kale can be sown, thinned, kept clean and harvested by machine. It can be harvested as required or ensiled. Thinned kale contains less dry matter but more protein, crude and true, and less fibre than unthinned. It contains from 11.5 to 16.7 per cent. dry matter, 9.1 to 15.7 per cent. crude protein and 18.0 to 23.0 per cent. fibre. Digestibility coefficients with wethers were, per cent.: dry matter 76, crude protein 75, fibre 52 for unthinned and, in the same order, 79, 81 and 57 for thinned kale. With heavy manuring, the unthinned crop yields about 15 per cent. more feed units per unit area than the thinned but 8 per cent. less digestible crude protein: less heavily manured, a thinned crop gives 5 per cent. more feed units and 24 per cent. more digestible crude protein.—I. Leitch.

ŠKORPÍK, P. and SEDLÁČEK, J. Stanovení krmné hodnoty pokrutin z jader peckovitého ovoce. [**The nutritive value of kernel cakes from stone fruits.**] *Sborn. čsl. Akad. Zěměd.*, 1954, **27**, 39–52. Russian and German summaries.

Kernel cakes from stone fruit cannot be used to replace the whole of the protein concentrates in rations for fattening pigs. If this is done the ration becomes unpalatable, the animals go off their food and the utilisation of what is eaten is reduced. It is probable that these cakes could be used if introduced gradually, mixed with the other concentrates and not allowed to exceed 350 to 400 g. per head daily. The cakes can also be used in limited amounts in a concentrate mixture for cattle. Sheep will tolerate a ration containing 750 g. of these cakes per head daily without showing any distaste or suffering in health.

The cakes vary in composition and nutritive

value according to the material from which they are made. Their economic importance in possibly saving the import of protein-rich foods is discussed. [From summary.]—W. Godden.

ISAJEV, F. Získávání náhradních druhů krmiv za současné situace. [**Substitute forages.**] *Veterinářství*, 1953, **3**, No. 5, 107–108. [Res. Inst. Animal Prod., Uhřetěves, Prague.]

For pigs and cattle small amounts of brewer's yeast, with a content of 7 per cent. digestible protein, may be used. Whey may be given in large amounts. Preparations from claws, hoofs, horns and feathers, and of the pancreas after the production of insulin, contain large amounts of amino-acids. Waste from bakeries, factories for sweets and flour products, and mills may be used for larger pigs and cattle after boiling. Waste after the cleaning of clover seed contains up to 19 per cent. digestible protein.

Ant. Jančařík (Czechoslovakia).

CLEGG, M. T. and COLE, H. H. **The action of stilboestrol on the growth response in ruminants.** *J. Animal Sci.*, 1954, **13**, 108–130. [Dept. Animal Husb., Univ. California, Davis.]

Yearling Hereford heifers and 2-year-old steers and Hampshire lambs were used in a series of 12 experiments to determine the effects of stilboestrol implants on rate of gain, economy of feed utilisation, endocrine weights, growth and adrenocorticotrophic hormone content of the pituitary, gland histology, N retention and differential blood counts. In all 340 animals were treated and a corresponding number were used as controls. The cattle received implants of 60 or 120 mg. stilboestrol and the lambs 12 or 24 mg. In the different experiments the diets were varied so that some animals were maintained on irrigated pasture with or without supplements and others on hay and concentrates indoors.

Supplemented stilboestrol-treated steers and heifers on pasture and in the feed lot made greater gains than controls or treated steers on pasture alone. The growth response of treated heifers was not so marked as that of steers. Weight gains of castrated male and intact female lambs exceeded those of the controls. Rate of gain of ewe lambs given 24 mg. stilboestrol was less than that of lambs given only 12 mg. Treated steers and heifers consumed more feed and utilised it more efficiently than did the controls. A further improvement in efficiency of feed utilisation was obtained when an additional 60 mg. stilboestrol was implanted 66 days after the first treatment. N retention in steers increased after treatment. A comparison of the carcasses showed that a greater percentage

N.A. and R., July 1954

of the higher carcase grades was found among the untreated steers, heifers and ewe lambs.

The weights of the pituitary and adrenal glands were significantly greater than those of the controls. In treated heifers thyroid weights were depressed. The amount of growth hormone present in the pituitaries of treated heifers was about twice that in the controls.—J. N. Aitken.

3845

HENNAUX, L., HOLVOET, J., LECOMTE, R. and HENIUS, J. M. Les agents modificateurs de la fonction thyroïdienne et l'engraissement des animaux domestiques. [**Agents affecting thyroid function and the fattening of domestic animals.**] *Bull. Inst. agronom. Gembloux*, 1953, **21**, 58–88.

Five experiments were made with pigs, 2 with cockerels and 1 with sheep to investigate the effects of adding antithyroid and thyroid compounds as supplements to basal rations. Theoretically antithyroid compounds should favour fattening and iodinated compounds should favour growth. An experiment in which pigs at a weight of 50 kg. had iodinated casein, 0.066 or 0.132 per cent. of the ration, for 3 weeks and then 0.2 per cent. methylthiouracil for 8 days produced carcasses with a better commercial value than controls; the carcasses of pigs given antithyroid compounds only were not so good as the controls. Propylthiouracil administered to 10-week-old chickens at a level of 0.05 and 0.15 per cent. for 4 weeks favoured fattening, improved market value, reduced consumption index and retarded testicular activity. The combination of stilboestrol with thiouracil gave even better results. One single experiment with 4 adult male castrated sheep which were given 1.4 g. methylthiouracil daily showed that this dose added to the specified ration favoured fattening and gave a good carcase.

It is emphasised that care should be taken before adopting a regime of thyroid and antithyroid administration. In pigs the results with antithyroid compounds were not good, with cockerels the results were favourable and with sheep the result was promising.—B. W. Simpson.

STOB, M., ANDREWS, F. N., ZARROW, M. X. and BEESON, W. M. **Estrogenic activity of the meat of cattle, sheep and poultry following treatment with synthetic estrogens and progesterone.** *J. Animal Sci.*, 1954, **13**, 138–151. [Dept. Animal Husb., Agric. Exp. Stat., Purdue Univ., Lafayette, Ind.]

Cattle, sheep and chickens were treated with synthetic oestrogens or progesterone, and tissues were assayed for oestrogenic activity.

In cattle with 60 or 120 mg. stilboestrol or 80

mg. dienoestrol subcutaneously implanted 140 days before slaughter, only the higher level of stilboestrol caused oestrogenic activity in the muscle. In liver from all treated animals oestrogenic activity was found. In another trial, in which treatment was with 108 mg. stilboestrol, 120 mg. dienoestrol or 300 mg. progesterone, oestrogenic activity was found in all samples of muscle. Cooking did not reduce the activity.

After treatment with 12 mg. stilboestrol 70 days before slaughter, there was oestrogenic activity in the muscle, but not in the liver, of lambs. In a second trial lambs were implanted with 12 or 24 mg. stilboestrol in the neck, ear or scrotum, and slaughtered 4, 8 or 12 weeks after treatment. At the lower level there was oestrogenic activity in the muscle, but only after 12 weeks. With 24 mg. stilboestrol there was activity in the muscle after 4 and 12 weeks but not after 8 weeks. There was no relation between the site of implantation and the amount of residual hormone.

Chickens were given implants of 12-mg. pellets of stilboestrol and whole carcasses were assayed 1, 2, 3 or 4 weeks after treatment. There was considerable retention of the hormone, but, in contrast to sheep, this was greatly reduced with time. Since the whole carcasses were used, some of the stilboestrol detected may not have been absorbed.

It was calculated that the residual hormone would not exceed 0.01 μ g. per g. dried tissue, which would probably be safe for human consumption.

MOORE, H. I. and CRADDOCK-TURNBULL, J. N. **Silage for winter feeding.** *Agriculture, J. Minist. Agric. Engl.*, 1954, **60**, 458–462. [Seale-Hayne Agric. Coll.]

Over the past 5 years the Seal-Hayne College Farm has attained a high degree of self-sufficiency. This is largely due to the use of arable crop and grass silage, which supplies 38 per cent. of the starch equivalent and 45 per cent. of the protein equivalent for cattle and 28 and 32 per cent. for sheep. Potato silage is given to pigs. Typical examples of the rations are shown. Silage for winter feeding has proved economical and animal production is maintained at a high level.

3852

FERRARI, E. Gli sprechi nell'alimentazione del bestiame. [**Wastage in animal feeding.**] *Riv. Zootec.*, 1954, **27**, 47–49.

The three most common causes of waste in animal feeding are insufficient preparation of roughages and grain, unbalanced rations and feeding beyond requirements. Hay and straw should be chopped, grains crushed or ground and roots cooked. Cooking protein concentrates reduces digestibility. The nutritive ratio of the ration should be related to the requirements of the stock, and the same applies to the amounts given, particularly as regards dairy cattle and their milk yield. Due consideration of these points would greatly reduce wastage and economic loss.—T. D. Bell.

DEPARTMENT OF AGRICULTURE FOR SCOTLAND, THE SCOTTISH HILL FARM RESEARCH COMMITTEE. **Hill farm research. Second report.** H.M.S.O., Edinburgh, 1953, pp. 108. Price 3s. 6d. net.

This committee was concerned with all aspects of hill farming, including vegetation on the hills and adjacent low ground, problems encountered in the management of sheep and cattle and the interrelationship of these animals under hill grazing conditions, economic studies, drainage and afforestation problems. With regard to heather, special emphasis is placed on the ecological survey at present in progress, and recommendations include field experiments when they become practicable as part of a programme for the study of moorland management and for increasing information on nutritional requirements of different breeds of hill sheep. In discussing mineral deficiency it is suggested that the extent of cobalt deficiency may be greater than is realised and attention should be paid to clinical surveys and experiments with cobalt on a large scale. Aerial topdressing and reseedling are discussed chiefly in the light of New Zealand experience, but no recommendation is made. Recommendations include the appointment of a scientific officer to direct hill farming research and promote the co-operation of specialist scientific workers at agricultural colleges, university departments and research institutes on the 3 hill farm research stations at present administered by the agricultural colleges. A brief study was also made of Welsh hill farming conditions. There are useful tables of hill sheep distribution and a list of hill plants with their botanical names and the English, Gaelic and Welsh equivalents.

CATTLE

GROWTH AND FATTENING

3860

HIBBS, J. W., CONRAD, H. R. and POUNDEN, W. D.

A high roughage system for raising calves based on the early development of rumen function.**2. Growth, feed consumption, and utilization by calves fed a 3 : 2 ratio of hay to grain with or without molasses or penicillin supplement.**CONRAD, H. R. and HIBBS, J. W. **3. Effect of rumen inoculations and the ratio of hay to grain on digestion and nitrogen retention.** *J. Dairy Sci.*, 1953, **36**, 1319-1325 ; 1326-1334. [Ohio Agric. Exp. Stat., Wooster.]

2. The high-roughage system used has already been described (see Abst. 1266, Vol. 24).

In this study the growth of 3 male and 3 female Jersey and Holstein calves fed on hay and grain in the ratio 3 : 2 was compared with the Ragsdale standards. The effect of adding either molasses or penicillin to this ration was also studied on 18 Jersey calves. Feed intake, height at withers and bodyweights were recorded during the first 12 weeks.

A further comparison was made between Jersey and Holstein calves given the 3 : 2 hay-grain ration to 12 weeks of age and subsequently a 2 : 1 ration of hay and grain to 26 weeks of age. All calves were given whole milk to 7 weeks of age and a grass-legume hay and a grain concentrate mixture thereafter. The calves were inoculated with rumen micro-organisms as previously described.

The growth of all calves at 12 weeks of age and of those maintained to 26 weeks of age was slightly below Ragsdale standards. The addition of molasses or penicillin to the 3 : 2 hay-grain ration had no significant effect on growth, feed consumption, or efficiency of feed utilisation. No difference in efficiency of feed utilisation was noted between the Jerseys and Holsteins during either of the periods.

3. Jersey bull calves, which had been reared on modifications of the high-roughage system already described, were used. The digestibility of dry matter, protein and cellulose and nitrogen retention in 2 eud-inoculated and 2 uninoculated calves and in calves given different types of hay-grain rations with the ratios of hay to grain 4 : 1, 3 : 2, and 2 : 3 were investigated.

The digestibility of protein was increased in inoculated calves given low-protein rations or when the protein source was mainly alfalfa hay. Nitrogen retention was not affected by rumen inoculation.

Differences in the digestion of protein by inoculated and uninoculated calves were eliminated

when the ratio of hay to grain was changed from 4 : 1 to 3 : 2 or 2 : 3. When alfalfa hay or clover-timothy hay was given in a 4 : 1 ratio, N retention per 100 lb. bodyweight decreased. There was an increase in N retention when the ratios of both hays were changed to 3 : 2 or 2 : 3.

Cellulose digestion decreased when the 2 : 3 ratio of hay to gain was compared with the 3 : 2 or 4 : 1 ratio.

The implications of the results are discussed in relation to rumen physiology.—J. N. Aitken.

3861

MANELLI, L. **Sull'allevamento delle vitelle e delle manzette. [Rearing of calves and heifers.]** *Zootec. Vet.*, 1954, **9**, 57-59. [Az. Agric. Cascina Bella.] English summary.

Whole and skimmed milk and a commercial milk powder for rearing calves for the first year of life were compared. Groups of 6 calves were reared from birth to 12 months.

The first group had whole milk, rising to a maximum of 10 litres daily, for the first 3 months and had access to first quality alfalfa hay after 40 days ; a vitamin supplement was given with the milk. During this period the average daily liveweight increase was 900 g. They were then weaned gradually to concentrates (bran, linseed cake and oats) for one month, and for the remaining 8 months they had good hay only. For the last 9 months daily liveweight increase was 600 g.

The second group was treated similarly for 2 months, when they were gaining 800 g. daily. For the next 2 months the whole milk was replaced by skimmed milk. Daily liveweight increase was 700 g. From 4 to 12 months they had hay and gained 600 g. daily.

Group 3 had 5 litres whole milk daily for one month, gaining 500 g. a day. For 2 months they then got 700 g. of a commercial milk powder, gaining 380 g. daily, followed by a month on concentrates as in the first 2 groups, and finishing on hay. The rate of daily gain was 450 g.

The fourth group was treated as the first, but only 5 litres daily of whole milk was allowed during the first 3 months. They gained 500 and 450 g. daily during the first 3 and last 9 months, respectively.

In body measurements and final liveweights groups 1 and 2 were greatly superior to groups 3 and 4, and the cost of 1 kg. liveweight increase was much less.—T. D. Bell.

3862

HANCOCK, J. **Studies in monozygotic cattle twins.** **10. General summary.** *N.Z. J. Sci. Technol.*

[4], 1953, **35**, 189-198. [Dept. Agric., Ruakura Animal Res. Stat., Hamilton, N.Z.]

This is a brief review of recent literature on cattle twins with special reference to frequency of monozygotic twinning, methods of diagnosis, twin efficiency values and heritability studies. The general conclusion is that, although the frequency of monozygotic twinning is low, sufficient numbers can be collected in any dairy cattle population to make large-scale investigations possible. Results from uniformity trials have shown the superiority of monozygous twins to unrelated animals as experimental material.—J. N. Aitken.

3863

KING, J. W. B. **A feeding experiment with twin cattle.** *Proc. Brit. Soc. Animal Prod.*, 1953, 76-84 (with discussion 84-85). [Animal Breeding Res. Organiz., Edinburgh.]

3864

KIDWELL, J. F. **Some growth relations in range cattle.** *J. Animal Sci.*, 1954, **13**, 54-60. [Dept. Animal Husb., Nevada Agric. Exp. Stat.]

Weight gains of cattle from weaning, fed through 2 winters, were studied in 4 periods: wintered on native hay, grazed on the range during the summer, grazed on aftermath during the autumn and finally wintered again on hay.

There was a positive correlation between the gains made during the 2 winter periods, and the correlations between any 2 successive periods were also significant, but negative, which suggested an inverse relation between adaptability to winter feeding and to summer grazing when there is a big change in environment. There was a high positive genetic correlation between gains in the winter feeding periods, indicating inheritance of adaptability, but in general environmental correlations were greater than genetic.—T. D. Bell.

3865

WINCHESTER, C. F. and HENDRICKS, W. A. **Energy requirements of beef calves for maintenance and growth.** *U.S. Dept. Agric. Tech. Bull.* No. 1071, July 1953, pp. 18. [Bur. Animal Indust., Agric. Res. Admin.]

Of 16 pairs of identical twin calves, aged between 3 and 6 months and weighing from 130 to 540 lb., one of each was fed below maintenance level, and the other above. Growth rates and total digestible nutrient (TDN) intakes were recorded. From the data the following equation for the estimation of the energy requirements of beef calves was derived:

$$f = 0.0553 w^{\frac{1}{2}} (1 + 0.805 g),$$

where f is the energy requirement in lb. TDN, w is

the bodyweight in lb. and g is the daily gain in lb. The energy requirement for maintenance is given when $g = 0$. A table computed from the equation for bodyweights for 200 to 800 lb. and daily increases from $\frac{1}{2}$ to 2 lb. is presented.—T. D. Bell.

3866

SEN, K. C., MURTHY, G. K., PREMACHANDRA, B. N., DASTUR, N. N. and RAY, S. C. **Effect of feeding iodinated casein on growth and food utilization by calves.** *Indian J. Dairy Sci.*, 1953, **6**, 201-216. [Indian Dairy Res. Inst., Bangalore.]

Heifers of the Gir and Sindhi breeds were divided into 2 comparable groups of 10 animals each. The animals in both groups were then divided into subgroups comprising those below or above one year of age. Iodinated casein was given to the experimental group at the rate of 2 g. per 100 lb. bodyweight for 26 weeks. During a further 10 weeks the iodinated casein supplement was increased to 4 g. per 100 lb. for 6 of the experimental animals and reduced to 1 g. per 100 lb. for the remaining 4 animals.

The rations of both groups during a 6-week pre-experimental period consisted of a concentrate mixture, mixed guinea grass and alfalfa, and ragi straw. When iodinated casein was given the amount of concentrates for both groups was increased by 25 per cent. Feed consumption and bodyweight were recorded. Digestibility coefficients and N balances were estimated in a metabolism trial with 6 control and 6 experimental animals. Growth rates of the treated animals were significantly reduced, more in older animals. Increasing the intake of iodinated casein caused a further reduction in the rate of growth. When the intake was reduced growth rate was accelerated. The treated animals consumed the same amounts of digestible crude protein and total digestible nutrients per 100 lb. bodyweight as the controls. Retention of N by the treated group was less than that of the control group.

It is concluded that induced hyperthyroidism raises the catabolism of body protein to supply energy, and as a result a significant amount of dietary protein is used to make good this loss instead of to support growth.—J. N. Aitken.

3867

KIDDER, R. W. and BEARDSLEY, D. W. **Protein and carbohydrate supplements for fattening steers on Everglades pastures.** *Florida Agric. Exp. Stat. Bull.* No. 493, May 1952, pp. 16.

Supplements of molasses, ground maize, cottonseed meal, and molasses with cottonseed meal for grazing Brahman steers were compared with grazing only in trials in 1947, 1948 and 1950. Only in the third year was the protein supplement

N.A. and R., July 1954

superior to the carbohydrate supplements. The supplemented animals were better than the unsupplemented in liveweight increase and carcass grade, and the financial returns were greater, though there was a reasonable return from grazing alone.—T. D. Bell.

3868

JOUBERT, D. M. **The influence of winter nutritional depressions on the growth, reproduction and production of cattle.** *J. Agric. Sci.*, 1954, **44**, 5-66. [Dept. Animal Husb., Univ. Pretoria.]

A general survey of work on animal nutrition done at the University of Pretoria over the past 20 years is given as an introduction.

The trials reported were made from 1948 to 1952. Friesian, Jersey, Shorthorn and Afrikaner heifers were kept on veld pasture, and during the winter half of them received supplementary feed. The treatments were referred to as high- and low-plane.

Growth on the low plane showed great seasonal fluctuation, closely related to the total digestible nutrient content of the pasture as shown by analysis. There were also distinct breed differences: on the high plane the Afrikanders gained fastest, but on the low plane the Jerseys were superior.

Low-plane nutrition retarded development, Shorthorns being most and Jerseys least affected. The relative increases in the summer were greater in the low-plane groups.

Age at first calving had no influence on the ultimate size of the animal, but during pregnancy weight increase was much less in the low-plane group, and the calves were lighter at birth. High-plane heifers could be served 9 months earlier than low-plane.

During lactation dairy breeds grew steadily, but beef breeds, suckling their calves, lost weight for 10 months. High-plane beef breeds lost relatively more than low-plane, probably owing to greater milk yields. Weaning weights of calves suckling low-plane dams were less than those suckling high-plane, but by 12 months of age there was no sign of prenatal influence. In milk yield and butterfat percentage there was no significant difference between high- and low-plane dairy cows, but the latter showed greater persistency.—T. D. Bell.

3869

ANDREWS, F. N., BEESON, W. M. and JOHNSON, F. D. **The effects of stilbestrol, dienestrol, testosterone and progesterone on the growth and fattening of beef steers.** *J. Animal Sci.*, 1954, **13**, 99-107. [Dept. Animal Husb., Agric. Exp. Stat., Purdue Univ., Lafayette, Ind.]

Vol. 24, No. 3

Three experiments were made with 120 Hereford steers. Steers which received subcutaneous implants of 60, 108 or 120 mg. stilboestrol or 80 mg. dienestrol, or a combination of 60 mg. stilboestrol and 200 mg. progesterone, made significantly greater weight gains than untreated controls. The administration of stilboestrol or dienestrol improved the efficiency of feed utilisation. The use of dienestrol and progesterone in combination in an injectable base had no significant effect. Steers which received a total of 255 mg. testosterone propionate did not gain as rapidly as controls. Treatment had no significant effect on dressing percentage. Carcass grade was reduced in some of the steers treated with stilboestrol. This treatment had the undesirable effect of elevating the tail head.—J. N. Aitken.

3870

ITTNER, N. R., LOFGREEN, G. P. and MEYER, J. H. **A study of pasturing and soiling alfalfa with beef steers.** *J. Animal Sci.*, 1954, **13**, 37-43. [Dept. Animal Husb., Imperial Valley Field Stat., El Centro, Calif.]

Rotational grazing, strip grazing, green soiling and wilt soiling as methods of using an alfalfa pasture seeded with barley were compared. There were 4 groups of 10 Hereford yearling steers. The trial lasted for 168 days. The rotational group was moved every 8 to 12 days, and the strip grazing group every 24 hr. The cut forage was allowed to wilt for up to 2 days for the wilt soilage group. Both the soilage groups were fed in dry lot. A small amount of oat hay was allowed to all to avoid bloat and scouring.

Daily gains in all groups were excellent and there was no difference between them. The amount of beef produced per acre was significantly greater by 36, 69 and 39 per cent. in the strip grazing, green soiling and wilt soiling groups, respectively, than in the rotationally grazed group.—T. D. Bell.

3871

HARDISON, W. A., REID, J. T., MARTIN, C. M. and WOOLFOLK, P. G. **Degree of herbage selection by grazing cattle.** *J. Dairy Sci.*, 1954, **37**, 89-102. [Dept. Animal Husb., Cornell Univ., Ithaca, N.Y.]

Holstein steers ranging in weight from 320 to 950 lb. were used in a series of trials with 6 herbages each at 3 to 5 different stages of growth. The basic design in all trials was to allow one group to graze herbage from the same source as that which was clipped and hand-fed to a similar group of stall-fed steers. Digestibility trials with all herbages were made on both hand-fed and grazing steers. The chromogen concentration of the faeces was used to estimate the amount and digestibility of the dry matter consumed by the grazing steers.

The faeces of the grazing steers contained significantly more crude protein, ether extract and ash and less crude fibre than the faeces of the hand-fed steers. All proximate constituents of the grazed herbage were more digestible than those of the clipped herbage. A reduction of the size of the area grazed tended to reduce the degree of selection. The content of crude protein and ether extract decreased and that of crude fibre increased as the herbage matured.

It was concluded that the chemical composition of clipped herbage is an unreliable index of the composition of herbage selected by grazing steers.

PERRY, T. W., BEESON, W. M., HORNBACK, E. C. and MOHLER, M. T. **Aureomycin for growing and fattening beef animals.** *J. Animal Sci.*, 1954, **13**, 3-9. [Agric. Exp. Stat., Purdue Univ., Lafayette, Ind.]

An aureomycin supplement of 24 mg. per 100 lb. liveweight given to suckling Shorthorn calves receiving a creep feed of maize, oats and soya bean meal to 80 days of age stimulated growth and reduced scouring, which was serious in the control group.

On a growing ration yearling Shorthorns got 63.5 mg. aureomycin per head daily for 14 weeks, 127 mg. for the next 6 weeks and 190.5 mg. for the last 6 weeks. They gained faster and converted feed more efficiently than controls.

When similar groups of Hereford yearlings, some on growing and some on fattening rations, each with or without 75 mg. aureomycin, were compared, on the growing ration those getting the antibiotic gained faster and were more efficient than the others, but on the fattening ration aureomycin had no effect.

Shorthorn calves and yearlings on a free-choice diet supplemented with 75 mg. aureomycin gained faster and were more efficient than controls, but when the antibiotic was introduced gradually, 25 mg. daily for the first week, 50 mg. for the second and 75 mg. thereafter, growth rate and efficiency were not improved.

There was a temporary depression of appetite for a few days in all trials when aureomycin was introduced.—T. D. Bell.

JOHANSSON, I. and HILDEMAN, S. E. Sambandet mellan vissa kroppsmaått och levande resp. slaktad vikt hos nötkreatur. [Relation between certain body measurements and live or carcase weight in cattle.] *Kgl. Lantbruksakad. Tidskr.*, 1953, **92**, 273-305. [Lantbrukshögsk. Inst. Husdjursetik.] English summary.

This paper deals with the prediction of liveweight and carcase weight in dairy cattle from

different body measurements. There is, as an introduction, a review of the literature on the subject. Dairy cattle from Swedish and Danish sources were measured.

The findings were that heart girth was most useful for predicting liveweight and was in fact as good as a combination of 2 more measures. It is suggested that it is preferable to use a series of linear equations each over a limited age range of the growing animal instead of a non-linear relationship to cover the whole range.

The errors in predicted liveweight and carcase weight are given along with the error obtained when the animal is weighed. A table is given which can be used to predict the liveweight and carcase weight from heart girth for lean, average and fat cattle. (From summary.)—A. W. Boyne.

CLIFTON, E. S. and SHEPHERD, G. **Objective grade specifications for slaughter steer carcasses.** *Iowa Agric. Exp. Stat. Res. Bull.* No. 402, November 1953, 540-568. [Ames, Iowa.]

The subjective method of carcase grading as used at present is not satisfactory in respect of uniformity of grading. In an attempt to grade carcasses objectively, measurements were made on 355 steers, including thickness of fat on eye muscle; body length, depth and weight; length of loin, width of shoulder and of round, circumference of round and area of rib eye. Correlation coefficients were calculated and estimations made on combinations of these to obtain the best criteria.

W. Thomson.

GREEN, W. W. **Relationships of measurements of live animals to weights of grouped significant wholesale cuts and dressing percent of beef steers.** *J. Animal Sci.*, 1954, **13**, 61-73. [Dept. Animal Husb., Maryland Agric. Exp. Stat.]

The wholesale cuts were grouped as follows: (1) round, trimmed loin and rib; (2) round, trimmed loin, rib and cross-cut. Liveweight was found to be closely associated with the weights of both groups of cuts. Width of shoulders and depth of twist were significantly and positively correlated with group 1 weights and both these measurements and width of hooks with group 2. Width of shoulders was significantly and positively correlated with dressing percentage.—J. N. Aitken.

MILK PRODUCTION

3879

HANSSON, A., CLAESSON, O. and BRÄNNÄNG, E. **Studies on monozygous cattle twins. 14. Milk secretion in relation to level of nutrition.** *Acta Agric. scand.*, 1954, **4**, 85-93. [Animal Breeding Inst., Wiad, Eldtomta, Sweden.]

Two pilot experiments are described. The twins used had been reared on the same plane of nutrition until first calving.

In the first experiment 3 twin pairs were used. All animals received the same maintenance ration relative to bodyweight. For milk production one member of each set received 0.35 and the other 0.45 Scandinavian feed units per kg. fat-corrected milk produced.

In the second experiment 6 twin pairs were used. The first member of each twin set to calve was used as control. The remaining 6 cows were placed in 3 groups of 2 animals each and were fed at levels of 80, 90, and 110 per cent. of that of the corresponding control animal.

The results from both experiments showed that a rising level of nutrition was accompanied by an increase in both milk yield and growth. The efficiency of feed utilisation fell as the level of nutrition rose.—J. N. Aitken.

3880

HANSEN, K. Afkomsprøver med tyre. 8. [**Progeny testing with bulls. 8.**] *Forsøgslab. København Beretn.*, 1954, No. 270, pp. 183. German and English summary.

All heifers are brought into as good condition as possible before calving on a ration of 4 feed units (FU) roots, 1 FU beet tops and 2 kg. of a mixture of 30 per cent. cake and 70 per cent. grain, varied according to the condition of the individual heifer.

During the winter the ration, from attainment of a yield of 10.5 kg. of 4 per cent. milk, consists of 1.5 FU swedes, 3.25 FU beet, 1 FU beet top silage, 2.5 kg. hay, concentrate mixture 1, and increasing amounts of concentrate mixture 2, at the rate of

0.4 kg. per kg. 4 per cent. milk. Mixture 1 was, per cent.: soya bean meal 15, cottonseed cake 20, groundnut cake 15, sunflower seed (expeller process) 17, linseed cake 8, coconut cake 18, fluid molasses 5 and dicalcium phosphate 2; mixture 2, per cent.: mixture 1, 35, wheat bran 15, barley 48 and dicalcium phosphate 2. The first provides 112 FU per 100 kg. and 306 g. digestible true protein per kg., the second 98 FU per 100 kg. and 148 g. digestible true protein per kg. For the first 6 weeks the cows are fed as if milk yield were 2 kg. above the actual yield.

In summer the cows are on pasture and, since its quantity and quality cannot be fixed, it is supplemented as appears necessary with roots, hay, silage and a concentrate mixture of 60 parts mixed grain, 30 oilcake and 10 molassed bran. Hence about two-thirds of production is in the winter under relatively highly standardised conditions and the rest under less uniform conditions. For the computation of feed consumption, summer supplements are recorded and pasture is "computed by the accepted rules" [not further described].

On the average of all the tests with Red Danish cows, winter milk production cost 0.41 FU per kg. 4 per cent. milk, with a range from 0.45 to 0.36. The most economical group put on 74 kg. weight and the least economical 25 kg. in the winter half-year. On the average, the protein allowance was, daily, 250 g. digestible true protein for maintenance and 120 g. for growth, and 60 g. per kg. 4 per cent. milk. The average consumption per kg. 4 per cent. milk was 68 g.—I. Leitch.

RAGAB, M. T., ASKER, A. A. and GHAZY, M. S. **Effect of age on total milk yield and length of lactation period in the Egyptian buffalo.** *Indian J. Dairy Sci.*, 1953, **6**, 181-188. [Dept. Animal Breeding, Fac. Agric., Fouad I Univ., Cairo.]

Milk records of a herd of Egyptian buffaloes were used and a statistical analysis of 923 lactations was made. The average age at first calving was 40.2 months. Total milk yields increased with increasing age at first calving. Milk production also increased with advance in age to the third lactation, after which it declined. Maximum production was attained in the third lactation. Absolute age and age at first calving had no effect on length of lactation.—J. N. Aitken.

3885

SEN, K. C., LAZARUS, A. J., RANGASWAMY, M. C. and ANANTAKRISHNAN, C. P. **Observations on some Indian cattle. 5. Cross-breeding for milk production.** *Indian J. Dairy Sci.*, 1953, **6**, 223-234. [Indian Dairy Res. Inst., Bangalore.]

Hariana, Sahiwal and Red Sindhi cows were crossed with Ayrshire bulls and the crosses were back-crossed with either Ayrshire or indigenous bulls to give animals with varying amounts of Ayrshire blood. The production performance of the crosses under tropical conditions was compared with that of the purebred native cows. A similar study was made with Friesian × Red Sindhi cows. The breeding programme extended over 40 years.

Crossbred cows produced more milk and had longer lactations and shorter dry periods than the purebred native cattle. Age at first calving rose as the amount of indigenous blood increased. The percentage incidence of foot and mouth disease and abortion increased as the amount of Ayrshire blood increased. Crossbred cows remained in the herd longer than did cows of the native breeds.—J. N. Aitken.

BOYD, L. J., SEATH, D. M. and OLDS, D. **Relationship between level of milk production and breeding efficiency in dairy cattle.** *J. Animal Sci.*, 1954, **13**, 89-93. [Kentucky Agric. Exp. Stat., Lexington.]

No significant correlation was found between the level of milk production during the first 120 days of lactation and the number of services required for successful conception when the breeding and production records of 225 Jersey, 208 Holstein and 86 Guernsey cows were analysed statistically.—J. N. Aitken.

3887

JARL, F. **Mineral metabolism in dairy cows.** *Kgl. Lantbrukshögsk. Ann.*, 1953, **20**, 151-203. [Nat. Animal Exp. Stat.]

Mature cows of the Swedish Red and White breed were used. The cows were depleted of P by being fed on a ration of hay, dried molasses, beet pulp and soya bean meal or peanut meal for 4 weeks before calving to 6 weeks after calving. During the first 6 weeks of lactation serum P fell to 1 or 2 mg. per cent. The availability of P from different sources was estimated in balance trials by giving equal amounts of P in the form of bone meal, dicalcium phosphate or disodium phosphate. The Ca:P ratio was kept constant by the addition of calcium carbonate. The availability of P in wheat bran, ground oats and a clover grass silage prepared by the addition of 1.67 per cent. of an acid salt was also estimated. The effect of vitamin D on the P balance was studied.

The P was equally well utilised whether it was supplied in the form of bonemeal, dicalcium phosphate or disodium phosphate or as an acid phosphate added as a preservative to silage. Blood P returned to normal within 10 to 14 days when 10 g. P was supplied as bonemeal, dicalcium phosphate or disodium phosphate. The availability of P in wheat bran and ground oats was significantly less than that of P as disodium phosphate. There was an improvement in P balance when the wheat bran ration was supplemented with vitamin D. Serum Ca was unaffected by the low P content of the feed. Ca retention was higher when mineral phosphates were given than when wheat bran and oats were used as the sole source of P.

MATHUR, M. L. and DESAI, S. V. **Studies on the effect of different fodders on the milk yield and its composition and mineral metabolism in Sahiwal cows.** *Indian J. Vet. Sci.*, 1953, **23**, 143-173. [Indian Agric. Res. Inst., New Delhi.]

The balance data, which refer to 4 high-yielding cows, were collected in 1946 and are in extension of work already reported in Abst. 2744, Vol. 17. A grain mixture to which supplements of NaCl and CaCO₃ were added was given according to requirements [feeding system not stated] and 4 roughages were used, green berseem (*Trifolium* sp.) manured with 329 lb. ammonium phosphate per acre, green unmanured berseem, green alfalfa, or jowar (*Sorghum* sp.) silage plus alfalfa hay. Balances of Ca, P, Na, K and Cl were studied for the latter 6 of the 12-day periods during which the roughages were given on the Latin square design. Methods of analysis are described and

N.A. and R., July 1954

full details of the results for each cow on each roughage are presented and summarised in 33 tables.

The different roughages were without significant effects on milk yield or bodyweight of the cows. Utilisation of each element was considered in terms of intake minus loss in faeces and urine. The mean intake of Ca for the 4 cows was highest during the period of manured berseem and it was then that the average balance was greatest; during the jowar silage plus hay period both intake and balance were lowest. Assimilation of Ca was between 15 and 30 per cent. of intake and was better on green berseem or alfalfa than on silage plus hay. Positive balances of Mg were maintained in all cows but one which was in the very early stages of lactation. Balances of P were negative except for 2 animals in their periods with manured berseem. In some of the cows balances of Na were negative during feeding of alfalfa and silage plus hay; the positive balances on green berseem were highly significant. Balances of K and Cl were positive with all fodders.

To maintain positive balances in cows producing between 30 and 40 lb. milk it is concluded that the following amounts of these constituents are needed in the daily ration: between 100 and 200 g. CaO, 80 g. MgO, about 100 g. Na₂O, 190 g. K₂O and between 112 and 130 g. Cl; for P₂O₅ 120 g. daily was not enough.—D. Harvey.

3889

DIJKSTRA, N. D., DAMMERS, J. and FRENS, A. M. Vergelijkende voederproeven met vet-arm en meer vet-rijk krachtvoer bij melkvee. [Comparative tests with low-fat and high-fat concentrates for milk cows.] *Versl. Landbouwk. Onderzoek.*, 1953, No. 59.6, pp. 63. English summary.

Three experiments were made each with 2 groups of cows and with 82 animals in all. For a long time before the studies began a low-fat concentrate mixture was given to the cows. In the first 2 experiments the procedure was the same. One group was given the low-fat mixture of extracted linseed, groundnut and coconut meals with other low-fat products throughout the 3 periods of the experiment; the other group was given this same mixture during the first and third periods but in the second it was replaced by one containing more fat and prepared from pressed instead of extracted meals. The third experiment differed by being in 4 periods, during the second and third of which changes were made also in the roughage.

In the first experiment 26 Friesian cows were used and the roughage given was silage and hay. Intakes of fat per cow daily were on the average 420 g. and 523 g. in the experimental period.

There was no difference between the groups in liveweight or condition and none of statistical significance in milk or fat production over the 28 days the periods lasted.

The second experiment was in 2 parts at separate centres with 22 Friesian and 12 M.R.Y. cows and with the first and third periods lasting 21 days and the experimental periods 56 days. Roughages were hay, fodder beet and rye straw; the low-fat and high-fat intakes were 144 and 172 g. and 288 and 306 g., respectively, at the 2 stations. There was little difference in weight and condition of the cows but at both centres production by the pressed cake group was higher than by the extracted cake group by 1.65 ± 0.28 and 1.00 ± 0.38 kg. milk and 63.6 ± 10.7 and 32.8 ± 14.2 g. fat per cow daily.

The third experiment of the same length as the second was with 22 Friesian cows and roughage was fodder beet, straw, and hay made from clover in the first part and from grass in the second part of the experimental period. The intakes of fat in these periods were 188 and 249 g. by the extracted cake group and 339 and 373 g. by the pressed cake group. The differences in milk production in these periods were 1.19 ± 0.24 and 0.92 ± 0.18 kg. and in fat production 46.8 ± 11.8 and 27.0 ± 9.5 g., in each case in favour of the pressed cake group.

It is concluded that the fat content of the roughage as well as of the concentrate mixture must be considered. According as the roughage consists of silage and certain hays or of other hays, fodder beet and straw and, as a consequence, is high or low in fat, the fat in the concentrate mixture may vary from 1.5 to between 4.8 and 5.8 per cent. The part that fermentation products of crude fibre may play in reducing the need for crude fat is briefly discussed.—D. Harvey.

3890

DAVIDOV, R. and ARISTOVA, V. Vliyanie ratsionov kormleniya korov na svoistva molochnogo zhira i kachestvo masla. [The effect of linseed cake in the ration of cows on the properties of butterfat and the quality of butter.] *Mol. Prom.*, 1953, 14, No. 10, 31-34. [Sel'khoz. Acad. Timiryazev, Moscow.]

Three groups of cows were given for 95 days well balanced diets, one a control and two of them with 140 and 240 g. linseed cake per kg. milk produced. The relative milk yields in the 3 groups were 100, 105.6, 111.1 and for fat content 100, 107.6, 112.4. Butter was made 5 times during the feeding period; samples were tested organoleptically, and bacterial counts, viscosity and the usual physicochemical constants were estimated on the fresh samples and after storage for 12 months at -10°C . The results are

tabulated. The butter from the milk of the group 3 cows was yellower in colour, and had a lower viscosity, lower saponification value and higher iodine number than that from the other 2 groups. It was of inferior keeping quality. It is recommended that the amount of linseed cake given should not exceed 140 g. per kg. milk.

W. Hughes.

3891

RAMSEY, D. S. and MILES, J. T. **Cottonseed vs. cottonseed meal and corn as a protein source in a concentrate mixture for dairy cows.** *J. Dairy Sci.*, 1953, **36**, 1308-1312. [Dept. Dairy Husb., Mississippi State Coll., State College.]

The 2 rations were compared in a double reversal trial of three 28-day test periods with 2 groups each of 9 Jersey cows and 1 Guernsey. The cottonseed ration consisted of equal parts of wheat bran, oats and whole cottonseed. In the control ration a mixture of 4 parts ground maize and 3 parts expeller-extracted cottonseed meal was substituted for the cottonseed on an equal weight basis. The mixtures were given at the rate of 1 lb. for each 3 lb. of fat-corrected milk produced. Hay and sorghum silage were given to appetite. Milk, butterfat percentage and body-weight were recorded.

When cottonseed was given milk production, fat-corrected milk production and butterfat percentages increased. Differences between the groups in roughage consumption and bodyweight gains were not significant.—J. N. Aitken.

3892

DALTON, H. L., HUFFMAN, C. F. and RALSTON, N. P. **The effect of feeding concentrates with different degrees of fineness and water contents on the eating and milking times in dairy cattle.** *J. Dairy Sci.*, 1953, **36**, 1279-1284. [Dept. Dairy, Michigan Agric. Exp. Stat., East Lansing.]

The concentrates were ground in a hammer mill using 1/16, 1/8 and 5/16 in. screens and water was added to the air-dry concentrates to make the ratio of water to concentrates 0.5:1, 1:1 and 1.5:1. In 1 trial 12 Brown Swiss cows were kept indoor for the experiment. In a second trial 11 Brown Swiss and 2 Holstein cows were used to study effects indoor and outdoor. The time required to eat the concentrates decreased as the ratio of water to concentrate increased. The degree of fineness of the concentrates had no effect on the eating time. There was a decrease in milking rate as concentrate consumption rate decreased. Cows on good pasture ate air-dry concentrates more slowly than under barn feeding conditions.—J. N. Aitken.

3893

BECKER, R. B. and ARNOLD, P. T. D. **Citrus pulp in dairy rations.** *Florida Agric. Exp. Stat. Circular* S-40, November 1951, pp. 6.

The uses of citrus pulp in rations for dairy cows are discussed. It is a carbohydrate feed fairly high in energy and Ca but deficient in protein and P. When it is included in balanced rations for cows consideration should be given to additional protein, P and other mineral supplements and green leafy roughage, either pasture, green hay or silage. Concentrate mixtures for use with citrus pulp are outlined.—J. S. Thomson.

3894

WAUGH, R. K., MOORE, J. L., LUCAS, H. L. and FAIRES, E. W. **Wood molasses as a feed ingredient for lactating dairy cows.** *J. Animal Sci.*, 1954, **13**, 44-48. [Dept. Animal Indust., N. Carolina Agric. Exp. Stat.]

Wood molasses produced from mixed hard woods by hydrolysis with sulphuric acid was given to lactating cows at levels of 10 and 20 per cent. of the concentrate mixture and in another trial at rates of 4 and 6 lb. daily. Control groups received no molasses. The molasses was well utilised by the cows and no deleterious effect was noted during 112 days. It was estimated that 1 lb. molasses could replace ½ lb. grain.—J. N. Aitken.

3895

FERRARI, E. **Erbe primaverili di marcita e alimentazione della bovina da latte.** [The spring grasses of the "marcita" and the feeding of dairy cattle.] *Riv. Zootec.*, 1954, **27**, 83-84.

In the spring there is very little clover in the "marcita" pastures. Analyses of 78 samples from the province of Milan, cut between March and June, gave the following average percentage composition, with the digestible percentage in brackets: dry matter 15.65, protein 2.27 (1.25), ether extract 0.89 (0.53), N-free extract 7.0 (5.0), fibre 3.80 (2.27). One quintal was equal to 9.80 feed units and the nutritive ratio was 1:7.1. From these data it was apparent that the forage was not suitable as the only ration for dairy cattle, since the nutritive requirements could not be met by the amount they could eat. The nutritive ratio was unbalanced for milk production, and protein intake would be insufficient. A table of suggested combinations of the forage and concentrates is presented.—T. D. Bell.

3896

LITTLE, C. J., NORDEN, A. J. and WOLCOTT, A. R. **Baled hay (field cured) compared with hay crop silage for winter feeding of dairy cows.** *Quart. Bull. Michigan Agric. Exp. Stat.*, 1953, **36**, 212-218.

Field-cured baled hay and silage made from the same crop and cut at the same time were compared for milk production, with 3 groups of 3 mature Holstein cows. The crop was of alfalfa, brome-grass, timothy and quack grass, and was harvested at the beginning of July. The results are presented in tables, and indicate that for milk yield and butterfat production there was no significant difference between the feeds.—T. D. Bell.

3897

BRUBAKER, R. E. and REAVES, P. M. **The effect of the ensiling process on wild onion and ragweed flavors in silage and in milk.** *J. Dairy Sci.*, 1954, **37**, 58-59. [Dept. Dairy Husb., Virginia Polytech. Inst., Blacksburg.]

Silage was made from mixed grasses containing 10 to 15 per cent. of wild onion (*Allium vineale*). Ground maize was added as preservative. The silo was opened after 56 days; the silage had a strong "pickled onion" smell.

A cow was given 10 to 12 lb. silage before milking on 4 successive days and consumed 5 to 7 lb. on each occasion before milking and the rest later. The milk was tainted with an onion flavour.

A second test was made using clover and wheat stubble silage containing 45 per cent. ragweed with molasses added as preservative. The milk was not tainted.—P. C. Jowsey.

STARKS, P. B., HALE, W. H., GARRIGUS, U. S., FORBES, R. M. and JAMES, M. F. **Response of lambs fed varied levels of elemental sulfur, sulfate sulfur and methionine.** *J. Animal Sci.*, 1954, **13**, 249-257. [Dept. Animal Sci., Univ. Illinois, Urbana.]

An experiment with 40 growing lambs to study the utilisation of inorganic S and urea N is described. The utilisation at different levels of elemental S 0.2, 0.4 and 0.6 per cent., sodium sulphate 0.89, 1.33 and 1.78 per cent. or DL-methionine 0.2, 0.5 and 0.7 per cent. was compared. Weight gains and wool growth of lambs treated with S, regardless of form, were significantly greater than those on the basal ration (92 per cent. N from urea, 0.054 per cent. total S). No statistically significant difference was noted between sources or levels of S given. The high levels of urea had no effect on blood urea.—J. C. Gill.

3909

CLARKE, E. A., BARTON, R. A. and WILSON, G. S. **The effect of highly improved and topdressed pastures on the thrift and production of sheep.** *Massey Agric. Coll. (Univ. New Zealand)*, 1953, pp. 92.

A large-scale study is reported of the effect on sheep and lamb production of grazing on high-producing pasture strains and on top-dressed pastures. In the pasture trials the following mixtures were used: (1) pedigree perennial ryegrass (p.r.g.) and pedigree white clover (high HCN); (2) pedigree p.r.g. and uncertified white clover (low HCN); (3) pedigree p.r.g. and mother white clover; (4) mother p.r.g. and mother white clover; (5) mother p.r.g. and pedigree white clover. Data on 16 ewes per group were collected over 4 years. Each of the 5 groups was moved rotationally round 4 one-acre plots. Extra stock were put on as required.

There were large differences in total amount and seasonal production between the 5 pastures and the superiority of the pedigree clover was not marked. Differences in stock-carrying capacity were highly significant. There was no significant difference between the groups on the different pastures in respect of ewe weights, ewe deaths, number and weight of lambs, carcase grade and

age at slaughter of lambs or in any fleece characteristic. No effect on stock from the clovers high in cyanogenetic glucosides was evident.

In the manuring trials the following treatments were given to simple ryegrass and white clover mixtures: (1) 1 cwt. superphosphate per acre per annum; (2) 4 cwt. superphosphate per acre per annum; (3) 4 cwt. basic slag per acre per annum; (4) 4 cwt. superphosphate per acre per annum with an initial 2 tons ground limestone and 5 cwt. annually thereafter; (5) as (4) with 2 cwt. of 30 per cent. potash salts per acre per annum. The sward was kept young and tender and at the most nutritious stage of growth. Data on 20 ewes per group, each group being moved rotationally round 5 one-acre plots, were collected over 7 years. Extra stock were put on as required.

There were large differences between treatments in pasture production and stock-carrying capacity. The superiority of ground limestone was most marked throughout each year, and also the effect of lime from the basic slag. Potash showed no beneficial effect. There was no significant effect on ewe, lamb or wool production.

It is thought that near perfect pasture control by extra stocking and mowing as required was achieved in these trials and the pastures were highly satisfactory for ewes and lambs. This control may be difficult to attain under commercial conditions.—J. C. Gill.

3910

THOMSON, D., CORNER, H. H. and CUNNINGHAM, J. M. M. **Silage for sheep.** *Scot. Agric.*, 1953-54, **33**, 155-159. [Cessford, Kelso.]

In trials over 3 years turnips were compared with grass silage for feeding pregnant and lactating ewes. The turnips group received 14 lb. turnips, 1 lb. hay and $\frac{1}{2}$ lb. concentrates before, and 20 lb. turnips, 1 lb. hay and $1\frac{1}{2}$ lb. concentrates after lambing. The silage group had 8 lb. silage before and 12 lb. after, with the same concentrates as the other group. There were 50 Half-bred ewes in each group each year. The feeding of roots began about 6 weeks before lambing and that of silage 2 or 3 weeks earlier. Liveweight increase was satisfactory in both groups, and lambs from both groups were equally thrifty and hardy, and had the same rate of liveweight gain. Fleece weights of ewes, milking and thriftiness when grazing after the supplements were discontinued were also similar in both groups.

On a practical scale, with a flock of 1300 ewes, roots were replaced by silage, fed to appetite, with some concentrates, and the results of the trials reported above were confirmed.—T. D. Bell.

STITT, W. A., PERRY, T. W. and BEESON, W. M. **Supplementation of farm roughages for pregnant ewes in dry lot.** *J. Animal Sci.*, 1954, **13**, 234-241. [Dept. Animal Husb., Agric. Exp. Stat., Purdue Univ., Lafayette, Ind.]

Three experiments with a total of 566 Hampshire × Rambouillet ewes are described. In trial 1 a basal ration of maize cobs supplemented with protein, carbohydrate, minerals and vitamins A and D was compared with a similar ration with vitamin B₁₂, the basal ration plus B vitamin complex and the basal ration plus alfalfa meal, as a feed for ewes during gestation and pregnancy. Ewes on alfalfa meal produced on the average 2 lb. more wool per head than those of the other groups and the vitamin B₁₂ group dropped and weaned a slightly higher percentage of lambs than the others. There was no significant difference in birthweight or in daily gain between the lambs.

In trial 2, a mineral and vitamin supplement was given with maize cobs, maize cobs and vitamin B₁₂, maize silage and grass silage. Ewes on maize silage gave significantly more wool than the cob groups and produced significantly larger lambs than did those on cobs or grass silage. The addition of vitamin B₁₂ to the ration with maize cobs was of no benefit. Again there was no difference in daily gain of lambs.

In trial 3, cobs plus sugar, cobs plus molasses, maize silage, maize silage plus sugar, maize silage plus molasses, and alfalfa hay were compared. Groups with a supplement of maize silage had heavier fleeces than cob groups and heavier lambs than any of the other groups. Ewes on alfalfa hay produced healthier and more vigorous lambs, which made a higher daily gain than the lambs of the other groups.—J. C. Gill.

3912

NEALE, P. E. **Alfalfa cubes for fattening lambs and wethers.** *New Mexico Agric. Exp. Stat. Bull.* No. 375, April 1953, pp. 17.

In the first experiment 6 groups of 20 lambs each were used. Half were hand-fed with medium-grade alfalfa hay and sorghum grain, and half were self-fed with cubes of low-grade alfalfa hay, sorghum grain and 10 per cent. molasses. The cubes were of 2 grades, the first with 60 per cent. hay and 30 per cent. grain, the second with 50 per cent. hay and 40 per cent. grain, and the lambs were changed from the first to the second after 25 days' feeding. The groups were divided into light, medium and heavy, according to initial liveweight of 70, 80 and 90 lb., and were fed to 100 lb. The trials were annually for 3 years. The average results showed that in rate of liveweight increase and efficiency of feed utilisation the self-fed groups were better than the hand-fed,

and the low-grade hay, incorporated in the cubes, was equal to the medium-grade fed separately.

In the second experiment, repeated for 3 years, wethers of average initial liveweight 74 lb. were fattened to 100 lb. There were 5 groups of 20 in each year. Groups 1 and 2 were hand-fed with sorghum grain, 1.0 or 1.25 lb., and medium-grade alfalfa hay to appetite. Group 3 had cubes of low-grade alfalfa hay 60, sorghum grain 30 and molasses 10 per cent., self-fed. Group 4 had cubes of low-grade alfalfa hay 50, sorghum grain 40 and molasses 10 per cent., and group 5 was fed as group 4 but grazed on irrigated alfalfa pasture. Group 3 was most efficient in feed utilisation and rate of liveweight increase. All self-fed groups were better than hand-fed, but the additional grazing in group 5 gave no advantage and was least economical.—T. D. Bell.

3913

PÁLSSON, H. Áhrif fangs á fyrsta vetri á vöxt og þroska ána. [The effects of pregnancy and milk production of yearling ewes on their growth and development.] *Rit Landbúnadardeildar, B-Flokkur*, No. 5, 1953, pp. 84. [Reykjavik.] English summary.

Ewes were mated at 7 months and slaughtered at 16 months of age. Carcasses were examined and the effects of pregnancy and suckling were investigated. For comparison there was a group which did not conceive, one which lost their lambs at birth, and one which suckled their lambs.

Early pregnancy and the strain of parturition retarded development and growth of fat, but did not affect conformation or growth and development of bone or muscle. The suckling of lambs resulted in lighter carcasses, and though the length of the long bones was not affected, their thickness and the growth and development of muscle and fat were retarded.

In the second part of the investigation ewes slaughtered at 28 months of age were compared. There were 5 groups: ewes which had never reared lambs; barren as yearlings and suckling singles in the second year; rearing one lamb as yearlings and again in the second year; rearing one lamb as yearlings and twins in the second year; and rearing one lamb as yearlings and none in the second year. The results indicated that the ewes retarded in the first year by rearing lambs were able to make up 60 per cent. of the loss during the second year, even when rearing another lamb, or twins. It is concluded that the practice of mating Iceland ewes at 7 months of age is justifiable. (From summary.)—T. D. Bell.

3914

BEESON, W. M., PERRY, T. W., STITT, W. A. and OUTHOUSE, J. B. **Antibiotic pellet implants**

for suckling lambs. *J. Animal Sci.*, 1954, **13**, 242-244. [Dept. Animal Husbandry, Agric. Exp. Stat., Purdue Univ., Lafayette, Ind.]

Two trials were made with 334 lambs in all. Subcutaneous implantation of lambs at 2 days of age with antibiotic pellets containing bacitracin or bacitracin and penicillin had no significant effect on growth rate. Implantation of lambs at 2 days of age or at 44 days of age with aureomycin pellets had no effect on growth rate.—J. C. Gill.

3915

RICHARD, R. M., SHUMARD, R. F., POPE, A. L., PHILLIPS, P. H. and HERRICK, C. A. **The effect of phlebotomy versus stomach worm, *Haemonchus contortus*, infection on the growth and certain blood constituents of lambs.** *J. Animal Sci.*, 1954, **13**, 274-282. [Wisconsin Agric. Exp. Stat., Madison.]

Blood was removed daily from non-infected lambs. The quantity removed was sufficient to keep the Hb values about the same as those of lambs artificially infected with *Haemonchus contortus* larvae. There were 4 different dietary groups.

In the infected lambs Hb, plasma nicotinic acid and vitamin B₆ values were reduced and growth was retarded. The removal of blood from non-infected lambs produced a similar effect. Lambs which received additional trace minerals, including Co, Cu, Fe and Mn, plus steamed bonemeal had less severe anaemia and showed better weight gains. Additional protein, with or without trace minerals, did not appear to have any effect.

G. C. Hunter.

3916

SPEDDING, C. R. W. **Effect of a sub-clinical worm-burden on the digestive efficiency of sheep.** *J. Comp. Pathol.*, 1954, **64**, 5-14. [Grassland Res. Stat., Stratford on Avon.]

Digestibility trials were made on 6 pairs of twin lambs. One of each pair was artificially infected with larvae of *Trichostrongylus axei*. The uninfected control lambs gained weight at a significantly greater rate than the infected. The general level of digestibility was lower in the infected lambs than in the controls. The apparent digestibility of crude protein was lower in the infected lambs; that of crude fibre showed no difference. The low liveweight gain was due chiefly to a considerable reduction of appetite and partly to reduction of digestive efficiency.

WHITING, F., NELSON, W. A., SLEN, S. B. and BEZEAU, L. M. **The effects of the sheep ked (*Melophagus ovinus* L.) on feeder lambs.** *Canad. J. Agric. Sci.*, 1954, **34**, 70-75. [Exp. Stat., Lethbridge, Alta.]

Two groups of 6 feeder lambs, one ked-free and one ked-infested, were well fed and one group of 6 lambs, ked-infested, were poorly fed 4 months in each of 3 successive years. In the third year there were 11 lambs in each group. In all 3 years the ked-infested lambs equalled the ked-free lambs on the same feeding level in liveweight gain and wool production. Ked populations on the poorly-fed lambs increased more rapidly and were larger than those on well-fed lambs. The number of keds on a sheep was not related to the suint or fat content of the fleece or to certain blood constituents.—J. C. Gill.

3918

EBERSÖHN, J. P. **Dorper sheep in the northern Cape Province.** *Farming in S. Africa*, 1953, **28**, 425-429. [Koopmansfontein Agric. Res. Stat.]

Dorper sheep have been bred from a Dorset Horn × Persian ram crossed with Blackhead Persian ewes, a project started in 1944. They are an admirable breed for the soil and climatic conditions of northern Cape Province. The ewes have been selected for fertility, milk flow and conformation. Growth curves of lambs and tables of age and liveweight are presented. Management is described.

Two head of cattle to 1 of sheep are grazed per morgen (2.1 acres), and since 1951, when regular dosing against worms and rotational grazing were introduced, marketable lambs of 75 lb. liveweight have been produced at 20 weeks of age. Average lambing percentage was 90 from 1947 to 1952, and the percentage of ewes in lamb after service was 95.—T. D. Bell.

3919

VENTER, J. J. **The necessity of sound growth in wool.** *Farming in S. Africa*, 1953, **28**, 374. [Grootfontein Coll. Agric., Middelburg, Cape Province.]

Ten sheep were used [breed not stated]. For a first period they received a good diet, then for a second period they were given a poor diet of veld hay and finally they received the good diet for a third period [duration of periods not given].

The average fineness of the wool was 22.2, 16.2 and 23.0 μ ., and the tensile strength under a strain of 106 g. per sq. cm. 1.09, 0.75 and 1.24 for the 3 periods. Between the good and poor feeding periods there was an average decrease in fibre thickness of 28 per cent. and in tensile strength of 37 per cent.

Although these results were obtained under extreme conditions, any reduction of feeding standards must have some adverse effect on wool quality.—P. C. Jowsey.

3920

BURNS, M. **Observations on the development of the fleece and follicle population in Suffolk sheep.** *J. Agric. Sci.*, 1954, **44**, 86-99. [Wool Indust. Res. Assoc., Headingley, Leeds.]

WALKER, D. E. **Elastration and other methods of castration in relation to carcass quality of fat lambs.** *N.Z. J. Sci. Technol.* [A], 1953, **35**, 360-367. [Ruakura Animal Res. Stat., New Zealand Dept. Agric., Hamilton.]

Five groups of fattening lambs were compared: castrated with elastrator at birth, with elastrator at 3 weeks, with knife at 3 weeks, with emasculator at 3 weeks, and not castrated. At slaughter carcass weights, measurements and grades were recorded.

Between groups there was no difference in any of the measurements, weights or proportions. In grading all castrated groups were equal but the entire animals were inferior, owing to poorer fat development. Subsidiary observations on mortality and disease also showed no difference between groups, and it was concluded that the different methods, if efficiently applied, are equally satisfactory as regards effects on carcass quality.

ROBINSON, J. F. **Survey of Blackface sheep with special reference to their hardiness. A report to the Scottish Hill Farm Research Committee.** H.M.S.O., Edinburgh, 1953, pp. 68. Price 2s. 6d. [Animal Breeding Res. Organiz., Edinburgh.]

Evidence submitted to the Hill Farm Research Committee in 1944 suggested that the decline in the numbers of hill sheep since the late nineteenth century was in part due to a deterioration in health and hardiness, and the main object of the survey was to obtain evidence of any change in the constitutional hardiness of Blackface sheep and, if such were found, to relate it to conditions responsible, such as changes in the sheep or in the ground or in the methods of breeding and management. Information was gained through personal visits, questionnaires and flock records for some 130 hill flocks representative of the main Blackface areas in Scotland south of the Caledonian Canal. Flock records going back 20 to 70 years were examined area by area, and the following conclusions were drawn.

In general the breeders thought that recent changes in type to the more compact fleece and body are proving beneficial. They were critical of the tendency to breed the Lanark type too big or to carry the reduction of fleece too far. The present tendency to judge Blackfaces more by

size, fancy points and carriage and to overlook qualities such as compactness and condition were deprecated and it was thought that if those methods are continued they may result in too long a body with narrow chest and loin, and so with loss of constitution and mutton qualities. The heavy feeding of tups by the tup breeders was deprecated. Though there was no clear-cut evidence that the use of these tups led to any loss of hardiness in the flocks, the mortality in the tups themselves was over 10 per cent. in average years. Over the years no evidence of loss of hardiness could be found through the level of stocking, prolificacy or mortality of ewes and lambs, nor was there evidence to suggest any deterioration in characters which make for survival in exceptionally severe winters.

The report contains useful tables of stocking rates, lambing percentages and mortality, and these demonstrate the profound influence of climate from area to area and year to year.

A further 20 visits made to breeders of Blackfaces and Swaledales in Northeast England revealed some evidence of a deterioration of Blackfaces, though not in mortality rate, since 1900, particularly in the Weardale area, where they have been replaced by Swaledales. This was thought to be partly due to using the wrong type of Blackface for this "harder" area. Lamb crops of Blackfaces were somewhat less than in South Scotland, and less than those of Swaledales. Swaledales suffered more severe losses than Blackfaces in the very severe winter of 1946-47.

SMITH, R. G. C. **Wintering Blackface ewe hogs. A further report on a Glensaugh experiment.** *Scot. Agric.*, 1953-54, **33**, 140-144. [N. Scotland Coll. Agric.]

The results of trials from 1949 to 1952 showed that ewe hogs wintered on reseeded low-lying hill pasture were in no way inferior to comparable sheep sent away for wintering on lowland pastures. Liveweight increases, lambing performances and wool production were compared. The only significant difference between the treatments was in the cost, those wintered at home being very much cheaper. (See Abst. 5654, Vol. 19 for the report of similar trials in 1944-48, of which these are a continuation.)—T. D. Bell.

3924

EDMUNDS, H. **Home wintering of hill lambs.** *Agriculture, J. Minist. Agric. Engl.*, 1954, **60**, 513-517. [Breconshire.]

On this farm at an elevation of 1150 ft. improvement in the cultivable land by the application of adequate lime and fertilisers and reseeded has

enabled all lambs to be wintered at home instead of having to be sent to lower ground as formerly. It has also been possible to grade some wether lambs off the hill and to increase the cattle and sheep stocks.—W. Thomson.

3925

Les problèmes de l'élevage ovin au Maroc. [**Problems of raising sheep in Morocco.**] *Zootechnia*, 1953, **2**, 363-372. [Serv. Élevage, Morocco.] Spanish and German summaries.

The position of sheep rearing in Morocco is critical. Common land is used, and overstocking has resulted in deterioration of pastures, which are insufficient for maintenance. Immediate action is necessary. Some research on the introduction of new forage crops and the improvement of those existing has already been done, and awaits general application. Suggested measures for the solution of the whole problem are the reduction of total stock, and particularly of the goat population, protection of pastures by correct management and consequent improvement of the stock reared, both

by selective breeding and as a natural result of better conditions. The necessary steps to be taken, and those which have already been taken by the authorities, are enumerated and discussed.

BECKER, D. E., ULLREY, D. E. and TERRILL, S. W. **A comparison of carbohydrates in a synthetic milk diet for the baby pig.** *Arch. Biochem. Biophys.*, 1954, **48**, 178-183. [Dept. Animal Sci., Univ. Illinois, Urbana.]

The carbohydrates, which made up 57 per cent. of the dry matter of the diet, were dextrose, lactose, sucrose, dextrin and maize starch. In the first test all of them were compared, with 7-day-old pigs. Rates of growth were greater, but not significantly so, on lactose and dextrin. The efficiency of feed conversion was significantly greater on lactose than on glucose or maize starch. On sucrose 3 of the 8 pigs died with severe diarrhoea but the survivors were almost as efficient as the lactose group.

The second test, with pigs of the same age as in the first, showed that an equal mixture of lactose and maize starch was slightly better than lactose alone and much better than maize starch alone.

In 2 further tests with 1- and 2-day-old pigs all those given sucrose died after 96 hr. on the diet, with severe diarrhoea and loss of appetite just before death. Control pigs given dextrose thrived.

BERGE, S. and INDREBØ, T. **Milk production by sows.** [Mjølkeproduksjon hos purker.] *Meld. Norges Landbrukshøgsk.*, 1953, **33**, 389-423. [Norges Landbrukshøgsk.] Norwegian summary.

The literature is reviewed and the technique and results of investigations are reported.

It was found that the quantity of milk secreted depended mainly on the size of the litter, sows with the larger litters giving more milk, but piglets in the smaller litters got more milk per head. The interval between sucklings is also important. When left to themselves, piglets suckled 20 times a day. In these investigations they suckled every hour, and milk production was about 50 per cent. higher than that found by other workers. The daily milk yield was less in the first week of lactation, and greatest in the fifth week, declining again towards the end.

During the third and fourth weeks the growth rate of piglets declined, but this could not be explained in terms of the amount of milk they were receiving. The highest rate of gain per kg. milk was during the first 2 weeks, and the lowest during the third and fourth. After that supplementary feed influenced the rate of gain. There was a high correlation between daily milk production and daily growth of litters.

Chemical analysis showed that colostrum was lower in fat and higher in total solids, particularly protein, than later milk, the average composition of which was: total solids 17.5, fat 6.1, protein 5.4, sugar 5.9 and ash 0.8 per cent.—T. D. Bell.

3931

EVANS, R. E. **Nutrition of the bacon pig. 17. The nutritive value of condensed fish solubles.**

N.A. and R., July 1954

J. Agric. Sci., 1954, **44**, 100-120. [Sch. Agric., Univ. Cambridge.]

A series of growth and nitrogen balance trials were made to investigate the value of condensed whale and fish solubles as sources of protein and as animal-protein factor (APF) supplements. Though the solubles are high in crude protein ($N \times 6.25$) only one-third of the N is true protein. The solubles were compared with white-fish meal, and in all experiments the diets supplied equal total digestible nutrients.

No evidence was obtained that the solubles given as 3 or 4 per cent. of an all-vegetable ration, in which the protein was supplied by soya bean meal, groundnut meal or dried brewer's yeast, acted as a source of APF, but it is possible that the lack of response was due to the pigs having body reserves carried over from the suckling period, or being able to synthesise APF.

When crude protein equivalent to 7 per cent. white-fish meal was supplied, the nutritive value of the crude protein of the fish solubles was inferior to that of the white-fish meal. This was shown in both growth and N balance trials. But the fish solubles were useful as a protein supplement for cereal grains. The unpalatability of the solubles, observed throughout the trials, may have contributed to its inferiority to white-fish meal.

GOBBLE, J. L. and MILLER, R. C. **Soft phosphate with colloidal clay in rations for swine.** *Pennsylvania Agric. Exp. Stat. Progr. Rep.* No. 93, February 1953, pp. 4.

Soft phosphate with colloidal clay is a residue from the mining of rock phosphate in Florida. It contains Ca 15 to 20, P 9, F 1.5 per cent., and may contain appreciable amounts of trace elements.

In feeding trials with pigs from weaning to slaughter at 290 lb. liveweight, 3 groups of 5 pigs each were given the same ration, except that in the first group the supplementary P was supplied by standard dicalcium phosphate and in the other two by soft phosphate and colloidal clay. The groups did not differ significantly in rate of liveweight increase, efficiency of feed utilisation, percentage ash in bone, percentage Ca and P in bone or inorganic P in blood. One of the soft phosphate groups received trace elements in addition, but with no apparent advantage. There was significantly more F in the bones of the soft phosphate groups, but there was no evidence of F poisoning, and the F level was not considered dangerously high.—T. D. Bell.

3933

TEAGUE, H. S. and HANSON, L. E. **The effect of feeding different levels of a cellulosic material**

Vol. 24, No. 3

to swine. *J. Animal Sci.*, 1954, **13**, 206-214. [Nebraska Agric. Exp. Stat.]

Three experiments were made with 24 individually fed, newly weaned pigs to test the effect on growth and digestibility of the nutrients of the ration of adding Ruffex, a cellulose preparation from rice straw, at levels of from 5 to 20 per cent. to a basal ration of maize starch, casein, lard, brewer's yeast, minerals and cod liver oil. Some of the pigs were slaughtered at 100 lb. and others at 200 lb.

The Ruffex up to a level of 10 per cent. had little effect on growth but higher levels adversely affected growth and feed utilisation, although there was considerable variation. Carcase characteristics were not affected. At levels of 15 and 20 per cent. Ruffex, the apparent digestibilities of the crude protein, ether extract and N-free extract were reduced. The digestibility of the Ruffex was poor and variable, with a tendency for more to be digested as the level was raised.—J. S. Thomson.

3934

DAMMERS, J. Varkensproef met het "Ergona-mestpreparaat". [Tests with pigs with the Ergona fattening preparation.] *Veeteelber.*, 1951, **5**, 1590; *Versl. Veren. Exploitatie Proef-zuivelboerderij Hoorn*, 1951-1952.

There are Ergona preparations, manufactured in Germany, for milk and egg production, for fattening and for growth. They are said to contain plant extracts in homeopathic quantities and consist, to the extent of 98 per cent., of calcium carbonate.

The fattening preparation was tested in an experiment with 3 groups of 6 pigs on a ration of cereals and whey, the second group like the first fed to appetite and the third on the same ration in restricted amount. The second and third groups had 20 g. Ergona per head daily. The pigs weighed about 75 kg. at the beginning of the test, after 70 days roughly 126, 131 and 111 kg., when the third group was returned to ordinary feeding and the other 2 groups transferred to a low-protein ration with a little grass. At 118 days their mean weights were 91.4 and 88.5 kg. There was no advantage in any respect from giving Ergona.—I. Leitch.

3935

ŠEVKOVIĆ, N. Uticaj animalne belančevine na korekciju uobičajenog obroka kod svinja u porastu. [Effect of animal protein in correcting an ordinary ration for growing pigs.] *Acta vet., Belgrade*, 1953, **3**, 145-149. [Inst. Tierernährung, Univ. Belgrade.] German summary.

Animal protein was given as boiled fresh horse-meat. The basal ration was a grain mixture of

maize, oats, barley and bran, with a little potato and 2 per cent. of CaCO_3 , a common ration in Jugoslavia.

The experimental group of pigs required 2.96 kg. feed per kg. gain as against 3.46 kg. in the control group. The importance of correcting the existing feeding practice and the financial advantage of such correction are urged.

S. Pribičević (Jugoslavia):

3936

HEWITT, A. C. T. **Feeding trials with whale solubles.** *J. Dept. Agric., Victoria*, 1954, **52**, 23-30; 36.

The whale solubles consisted of a black viscous liquid containing moisture 45 to 50, crude protein 42 to 48, crude fat 1 to 2 and mineral matter 4 to 5 per cent. It was mixed with the meals, and in one instance lumps had to be ground in a hammer mill because the pigs refused it.

Two trials with pigs of initial liveweight 30 lb. and 2 with pigs of 50 lb. were made to compare meatmeal and whale solubles as protein supplements to a cereal meal and alfalfa ration for growing and fattening. In 3 trials there were 3 groups, one getting meatmeal, one a mixture of meatmeal and whale solubles, and one whale solubles. In the fourth trial the second group was omitted. The protein supplement was about 8 per cent. of the ration.

With the lighter pigs the efficiency of feed conversion and rate of liveweight increase were not as good in the whale solubles group as in the other two, but there was no difference in dressing percentage or carcass appraisal. The same tendency was found in the heavier pigs, but the differences were slight.

Laying hens on grain and mash, with half or all the meatmeal in the ration replaced by whale solubles, put on more weight but laid fewer eggs in a 162-day period than those getting meatmeal only. Cannibalism was worse in the whale solubles groups.—T. D. Bell.

3937

VORSTER, T. H. **The effect of Lederle Aurolac on the growth of pigs.** *Rhodesia Agric. J.*, 1953, **50**, 375-378.

Lederle Aurolac containing not less than 1.89 g. of aureomycin hydrochloride and 1.8 g. of vitamin B_{12} activity per lb. was added to the ration of pigs from weaning to bacon weight at the rate of 5 lb. per ton feed. A control group had no Aurolac supplement. The basal ration was white maize meal 65, groundnut cake meal 12, cottonseed cake meal 10, wheat bran 7, fishmeal 5 and bone-meal 1 per cent., and green alfalfa was also given. The pigs were slaughtered at 180 to 190 lb. liveweight. The experimental group gained slightly

faster and were slightly more efficient in feed utilisation than controls, but the differences were not significant. There was no difference in carcass grade, but the dressed carcass weights were significantly higher in the experimental group. There was a saving of 5s. 8½d. per pig, and it is concluded that Lederle Aurolac must cost less than 5s. 9½d. a lb. to be economically worth while.—T. D. Bell.

3938

RUSSELL, L. and McClymont, G. L. **Antibiotics for stimulating growth in pigs.** *Agric. Gaz. N.S.W.*, 1953, **64**, 604-605.

Aureomycin in the ration of pigs for 122 days after weaning increased growth rate by 25 and efficiency of feed conversion by 8.3 per cent. compared with controls. Procaine penicillin did not improve performance in any way. There is a general discussion on the advisability or otherwise of using antibiotics, with reference to the stimulation of growth in runt pigs.—T. D. Bell.

3939

BARBER, R. S., BRAUDE, R. and MITCHELL, K. G. **Antibiotics and endocrine stimulants as promoters of growth in fattening pigs.** 2. *Chem. and Indust.*, 1954, No. 3, 76. [Nat. Inst. Res. Dairying, Univ. Reading.]

In continuation of experiments previously reported (Abst. 5253, Vol. 23), feeding trials were made to study the growth-promoting effects of L-thyroxine and an antibiotic, but no stilboestrol. There were 6 groups of 9 pigs each, of average initial liveweight 46 lb. They were fed for 16 weeks on a basal meal of fine wheat offals 50, barley meal 30, flaked maize 10 and white-fish meal 10 parts by weight, as a wet mash, given according to liveweight, with the following supplements: 0.3 mg. L-thyroxine; 1.1 g. Aurolac 2A; 5 mg. procaine penicillin; 0.3 mg. L-thyroxine and 1.1 g. Aurolac 2A; 0.3 mg. L-thyroxine and 5 mg. procaine penicillin. A control group had no supplement.

All the antibiotic and combined supplements significantly increased the rate of liveweight gain and efficiency of feed utilisation as compared with the control group, but the differences between the antibiotics and the combined supplements were not significant, though the results indicated that the addition of L-thyroxine did tend to improve performance. Further work is in progress.

DAMMERS, J. **Proeven over het gebruik van antibiotica voor mestvarkens.** [Experiments in the use of antibiotics for fattening pigs.] Centraal Veevoederbureau in Nederland, 1953, pp. 15. English summary.

N.A. and R., July 1954

Four experiments were made with fattening pigs. In the first, 0.1 per cent. of U.S.I. antibiotic feed supplement containing 5 g. bacitracin per lb. failed to increase the rate of gain or feed efficiency when added to a ration containing sufficient animal protein. In other experiments in which the ration contained all-vegetable protein, 0.25 or 0.5 per cent. of Aurofac, containing 1.8 g. aureomycin per lb., gave an 8 to 16 per cent. increase in growth rate and a 9 per cent. increase in feed efficiency. When the ration contained animal protein the increases were only 3 to 6 and 2 to 4 per cent., respectively. Similar results were obtained with terramycin. It is considered that antibiotics are effective for pigs in poor condition during the first half of fattening but that it is advisable to limit the application of antibiotics until more is known about their effect on the organism and of their continued use in successive generations. [From summary.]—W. Godden.

3941

FLETCHER, J. L. and BARRENTINE, B. F. **Antibiotic supplementation of corn-cottonseed meal rations for growing pigs.** *J. Animal Sci.*, 1954, **13**, 201-205. [Mississippi Agric. Exp. Stat.]

Five trials with pigs receiving aureomycin or penicillin supplements are reported. In all trials the basal ration was of maize, cottonseed meal, alfalfa meal and minerals, and 0.5 per cent. ferrous sulphate was included to prevent any toxic effect of cottonseed meal. Aureomycin was given at the rate of 6.8 or 13.6 mg. per lb. feed and penicillin at 2 mg. per lb.

In 2 trials with the lower level of aureomycin, growth rate and efficiency were increased; in a third, growth rate decreased but efficiency was better. The higher level decreased both growth rate and efficiency. The pigs in this trial were somewhat heavier than those in all other trials. In the 2 trials with penicillin growth rate and efficiency were increased. Both supplements contained vitamin B₁₂, and the response may have been partly due to this.—T. D. Bell.

3942

WALLACE, H. D., MILICEVIC, M., PEARSON, A. M., CUNHA, T. J. and KOGER, M. **The influence of aureomycin on the protein requirement and carcass characteristics of swine.** *J. Animal Sci.*, 1954, **13**, 177-183. [Dept. Animal Husb., Florida Agric. Exp. Stat.]

In a trial with 54 pigs of 40 lb. weight 3 levels of protein were compared, and at each level half the pigs were given 20 g. aureomycin supplement per 100 lb. feed. The levels of protein were 14.3, 17.6 and 20.9 per cent. up to 100 lb. liveweight,

and then 11.7, 14.3 and 17.6 per cent. to slaughter weight. The ration was of ground yellow maize, expeller soya bean meal, alfalfa leaf meal and minerals.

The low-protein group with aureomycin made slightly greater daily liveweight increases, but there was no significant difference between groups. In efficiency of feed conversion the medium protein group was best. Aureomycin improved performance only in the high-protein group.

Hb level was significantly higher in the medium- and high-protein groups, and aureomycin raised Hb in all groups, though not significantly.

At low and high protein levels dressing percentage was higher in the aureomycin groups, but the reverse was true in the medium groups. Between protein levels the differences in dressing percentage were significant: the high level dressed lower than the others. Aureomycin increased backfat thickness. The highest carcass grade was found in the high-protein group without aureomycin.

T. D. Bell.

3943

BRATZLER, L. J., SOULE, R. P. (Jr.), REINEKE, E. P. and PAUL, P. **The effect of testosterone and castration on the growth and carcass characteristics of swine.** *J. Animal Sci.*, 1954, **13**, 171-176. [Dept. Animal Husb., Michigan Agric. Exp. Stat.]

There were 6 groups of 40 lb. pigs, all self-fed on rape pasture and concentrates. The treatments were: (1) castrated at the beginning of the experiment; (2) as (1) and implanted with 193 mg. testosterone propionate; (3) castrated at live-weight 100 lb.; (4) at 140 lb.; (5) at 180 lb. live-weight; (6) left entire.

There was no difference between groups in daily rate of gain or efficiency of feed conversion. Groups 1, 2 and 3 had higher dressing percentages, owing to thicker backfat. Groups 4, 5 and 6 were longer in the body. Groups 5 and 6 had significantly higher percentages of preferred cuts and lean meat in the loin. In palatability, however, group 6 was much below the other groups. Castration as late as 5 weeks before slaughter (group 5) was considered adequate to eliminate the offensive properties of boar meat.

Kidney weights were greater the later castration was done, and greatest in the intact boars. This applied to weights of accessory sex glands also. The implantation of testosterone was without effect.—T. D. Bell.

TAKETOMI, M., NIWA, T. and ONISHI, N. [A statistical consideration on the litter-size in

swine, with special reference to its repeatability.] *Bull. Nat. Inst. Agric. Sci., Chiba, Japan* [G], 1953, No. 7, 147-152. In Japanese: English summary.

This is a statistical analysis of data for 635 litters of Middle White, Berkshire and Poland China pigs, from the breeding and farrowing records of pigs at the National Institute of Agricultural Sciences during 1927 to 1951. In all breeds litter size in the first litter was smaller than in successive litters. The general conclusion is that the hereditary difference should be less than 26 per cent. of the intra-breed variance. [From summary.]—W. Godden.

TAKETOMI, M., NIWA, T. and ONISHI, N. [On the heritability of bodyweight in pigs.] *Bull. Nat. Inst. Agric. Sci., Chiba, Japan* [G], 1953, No. 7, 153-160.

Data from the records of Middle White pigs at the National Institute of Agricultural Sciences collected over the periods 1929 to 1939, 1940 to 1942 and 1943 to 1948 were examined. They included the number of boars and sows used and the bodyweight of the pigs at birth and at 1, 2 and 6 months of age. In the first period all the boars except one were imported, but in the subsequent periods their descendants were used. Feeding and management were satisfactory in the first 2 periods but in the third were adversely influenced by the war. Differences in birthweight in all 3 periods were slight, but bodyweights at 1, 2 and 6 months of age were much lower in the period 1943-1948. The results indicate that the worse the environmental conditions, including feeding, the more clearly were the genetic differences seen. [From summary.]—W. Godden.

- 3954
RYASHCHENKO, L. P. [The effect of feeding *Laminaria* on the antlers of Spotted Deer.] *Karakul. i. Zver.*, 1953, 6, No. 2, 61.

Male spotted deer were found to eat *Laminaria* quite readily; of 8 test animals only 2 were not keen on it. Large quantities, up to 13 kg. per head daily, produced no abnormality of the intestinal tract. Continuous feedings with dried *Laminaria* at the rate of 1.29 kg. per head daily led to a good increase in bodyweight of the deer but decreased the growth of the antlers. The weight of antlers from test animals was 10.7 per cent. less than that from controls; when the antlers were stored this difference increased to 13.5 per cent. [From summary.]—W. Hughes.

MORRIS, M. L. Nutritive requirements of the cat. *Vet. Med.*, 1953, 48, 451-456; 1954, 49, 85-86. [Topeka, Kans.]

Thirteen male castrate well nourished cats were each given 135 g. daily of a "freshly-prepared raw meat-like" diet, and the weight of feed refused was measured. After 7 days, and for the following 11 days, this diet was withdrawn and replaced by 148 g. of a "carefully balanced but sterilised canned product", with a slightly different moisture content. The change did not cause significant changes in feed consumption or bowel movement.

Average daily energy consumptions were 53.8 Cal. for the raw and 43.1 for the canned diet.

N.A. and R., July 1954

Ash consumptions and excretions in the urine, both per 100 g. feed consumed, were, respectively, 1.8 and 0.81 g. for the raw, and 0.82 and 0.41 g. for the canned rations.

It is considered that these data may throw some light on the problem of urinary diseases associated with mineral deposits.—W. A. Greig.

3956

WOOLEY, J. G. **Growth of three- to four-week-old rabbits fed purified and stock rations.** *J. Nutrition*, 1954, 52, 39–50. [Nat. Inst. Arthritis Metabol. Dis., Nat. Inst. Health, Bethesda, Md.]

Groups of rabbits weaned at 3 to 4 weeks old and weighing 350 to 500 g. were fed to appetite for 4 weeks on a purified diet 1395 previously found satisfactory for 8-week-old rabbits by Wooley and Sebrell (Abst. 1354, Vol. 15) or on a purified diet 1436 similar to that found satisfactory by Reid and Briggs (Abst. 3515) for guineapigs. Other groups received these diets in which 40 per cent. of dried kale leafmeal replaced portions of the sugar, starch, fat and protein in the diets. A control group was fed on stock pellets.

Diet No. 1395 did not support good growth in the young animals but the introduction of 40 per cent. of kalemeal produced considerable stimulation of growth. Other vegetables were also effective but not to the same extent. After the first week the rabbits on stock pellets, diet 1395 with kale and diet 1436 with or without kale exhibited the same rate of growth. The addition of 0.2 per cent. of K as carbonate or acetate to diet 1395 stimulated growth but not to the same extent as the kalemeal.

Preliminary experiments indicated that with casein as the source of protein 25 per cent. is necessary in the diet for young rabbits but that equally good results are obtained at the 20 per cent. protein level if part of the casein is replaced by kalemeal.—W. Godden.

3957

BORTOLI, O. **Effetti della somministrazione di idrolizzato di corna sulla lana del coniglio d'Angora.** [The effect of administration of hydrolysates of horn on the wool of the Angora rabbit.] *Riv. Zootec.*, 1954, 27, 87.

As a source of cystine, a hydrolysate of horn, 0.5 g. for 40 days and 1.0 g. for a further 50 days, was given to adult Angora rabbits. A control group of the same strain received no supplement. All animals were plucked at the beginning of the experiment, and the wool grown was weighed after 90 days. There was a slight advantage of 1.52 per cent. in the experimental animals compared with controls, and the sulphur content of the wool was increased. Supplementation had no effect on liveweight, and all animals remained in good health.

There were only 12 animals in each group. Increases of 5.61 per cent. have been observed in castrated animals, and the matter requires further investigation.—T. D. Bell.

3958

MATRONE, G., WELDON, V. B., SMART, W. W. G. (Jr.), SHERWOOD, F. W., SMITH, F. H. and WISE, G. H. **Effects of phosphate fertilization and dietary mineral supplements on the nutritive value of soybean forage.** *J. Nutrition*, 1954, 52, 127–136. [Dept. Animal Indust., N. Carolina Agric. Exp. Stat., Raleigh.]

Soya bean hay, prepared by barn drying from crops grown in 2 different seasons with and without phosphatic fertilisers, were used. In both seasons the fertiliser caused a larger increase in the yield of dry matter per acre, a decrease in the percentage of leaf in the whole plant and an increase in the percentages of Ca and P in the dry matter. The rations given to 4-week-old, newly weaned rabbits were, per cent.: hay 76, cerelese 13, cottonseed oil 5 and egg albumin 6. The hays from the second-year crop were also given with and without the addition of 0.75 per cent. CaHPO_4 to the ration. The rabbits on the rations containing the unfertilised hay showed smaller liveweight gains over 7 or 11 weeks and had a lower serum inorganic P and their femurs had greater fragility and lower sp. gr. than those of rabbits receiving the fertilised hay. The addition of CaHPO_4 to the low-P forage ration eliminated these differences and gave greater liveweight gains than did a similar addition to the high-P forage ration.—W. Godden.

FANGAUF, R., KLEIN, F. W. and BARLÖWEN, G. v. **Über den Kochsalzanteil im Kükenallein-futter.** [Sodium chloride in all-mash rations for chicks.] *Arch. Geflügelk.*, 1954, 18, 33–36. [Lehranst. Kleintierzucht, Kiel, Steenbek.] English summary.

Four groups of 40 Single Comb White Leghorn

chicks were reared for 8 weeks on an all-mash ration to which was added 0.6, 1.0, 2.0 or 3.0 per cent. NaCl. Greatest growth was obtained at the 0.6 level. There was no effect on mortality, which was low in all groups. Raising the salt level increased water consumption and the moisture content of the droppings.—W. Godden.

3961

FRÖLICH, A. Kvalitetsbedömning av sojamjöl med laboratoriemetoder och i försök med kycklingar. [Assessing the quality of soya bean meal by laboratory methods and in chick experiments.] *Kgl. Lantbruksakad. Tidskr.*, 1953, **92**, 367–378. [Statens Husdjursförsök, Upsala.] English summary.

The dual problem of treatment of soya bean meal so as to destroy its antiproteolytic activity without denaturing its protein is outlined. Three samples of solvent-extracted meal, from the same dealer but probably not from the same factory, were tested for antitryptic activity, urease activity and water-soluble protein by formol titration and absorption of phenolphthalein, as received and after autoclaving for 20 or 60 min. at 1.5 atm. and 121° C. All samples were tested also in chick growth experiments. Two samples had been insufficiently heated in the first place and autoclaving for 20 min. raised their value to about that of the third sample in the chick experiments. There was a close correlation between laboratory and biological grading, especially with the phenolphthalein test. Details of it will be published elsewhere.—I. Leitch.

3962

ALMQUIST, H. J. and MERRITT, J. B. Accentuation of dietary amino acid deficiency by raw soybean growth inhibitor. *Proc. Soc. Exp. Biol. Med.*, 1953, **84**, 333–334. [Grange Co., Modesto, Calif.]

A diet with a marginal tryptophan content, containing 15 per cent. protein from meat scrap and 5 per cent. protein from raw soya bean meal, was given to chicks. Very much better growth was obtained if 0.2 per cent. L-tryptophan was added, though not as good as that resulting from heating the soya bean meal, the average weights at 28 days being 131, 254 and 354 g., respectively.

The experiment of Hill *et al.* (Abst. 5283, Vol. 23) was repeated with methionine and arginine instead of the mixture of 11 amino-acids, to procure a better balance of amino-acids, and a growth period of 28 days instead of 7, to avoid effects due to continued assimilation of yolk. The average weights at 28 days of chicks on the basal diet, on the basal diet with methionine and arginine, and on the basal diet containing heated soya bean

meal were 247, 307 and 316 g., respectively, in contrast to the findings of Hill *et al.* that added amino-acids had no effect.—C. Warner.

3963

FISHER, H., SCOTT, H. M. and HANSEN, R. G. Further studies on the alfalfa factor and its relation to the liver and whey factors. *J. Nutrition*, 1954, **52**, 13–24. [Dept. Animal Sci., Illinois Agric. Exp. Stat., Urbana.]

In extension of earlier work (Absts. 5276, 5277, Vol. 23) it is shown that alfalfa meal, defatted whole liver and dried whey each contain separate and distinct growth factors for chicks which are additive in their action. Of the 3 supplements alfalfa meal gave the greatest and most consistent response, which could not be explained on the basis of the alfalfa meal's content of ash, critical amino-acids or glucuronic acid.

W. Godden.

3964

DAVIS, G. K., MEHRHOF, N. R., DRIGGERS, J. C. and DENNISON, R. A. Dehydrated celery tops in chick rations. *Florida Agric. Exp. Stat. Circular S-37*, October 1951, pp. 6.

In experiments extending over 3 years dehydrated celery tops, a waste product from the vegetable growing industry, were given to chickens at levels of from 3 to 11.3 per cent. of an all-mash basal diet and growth was compared with that on the basal diet with 6 per cent. alfalfa leaf meal.

Up to 10 weeks of age there was no significant difference between the groups in growth, mortality or efficiency of feed conversion.

On a moisture-free basis celery was higher than alfalfa meal in Ca, P, Mn and carotene, but up to 45 per cent. of the carotene may be lost after 5 months' storage.—J. S. Thomson.

3965

O'NEIL, J. B. and BELL, J. M. "Feed-Ani" as a ration component for poultry and livestock. *Canad. J. Agric. Sci.*, 1954, **34**, 36–40. [Dept. Poultry Husb., Univ. Saskatchewan, Saskatoon.]

"Feed-Ani" is a naturally occurring mineral deposit obtained in Nevada, U.S. It contains about 80 per cent. silica compounds, about 0.3 per cent. F and traces of the "essential" minerals.

Experiments with chicks showed that their growth was depressed by an amount roughly equivalent to the dilution of the feed by "Feed-Ani" added at a rate of 2 per cent.

In a test with mice, feed consumption increased on the average by 13 per cent. but no improvement in weight gain was noted. "Feed-Ani" caused a significant decrease in feed efficiency.

Further studies with poultry are in progress.

P. C. Jowsey.

3966

SLINGER, S. J., HAUSER, M. M. and PEPPER, W. F.
The correlation between feed consumption and fecal flora in chicks. *J. Nutrition*, 1954, **52**, 75-88. [Dept. Poultry Husb., Ontario Agric. Coll., Guelph.]

A group (A) of 18 chicks was housed in a wire-floored cage and fed to appetite from day-old to 7 weeks on a ration containing 6 per cent. animal products, 28 per cent. soya bean meal and supplementary methionine. A similar group (B) received the same treatment but with a dietary supplement of 15 mg. procaine penicillin G per kg. Two further groups (C and D) received the same treatments, but with their feed intake restricted to that of group A for the first 4 weeks of the trial.

At 4 weeks of age the mean liveweights of the groups were 394, 431, 376 and 377 g., respectively. Feed consumption of group B, whether expressed "per chick" or "per 100 g. bodyweight", was higher than that of group A, over the first month. At 7 weeks of age the mean weights of the 4 groups were 939, 1036, 933 and 959 g., respectively. When growth was calculated on a logarithmic basis for the period from 4 to 7 weeks of age it was only 1 per cent. greater for group B than for group A.

In the first 4 weeks of the trial mixed daily samples of droppings were taken from each group, and bacteriological examinations were made of these after serial dilution in a number of different media. The counts of coliform bacilli in the droppings of group B remained consistently higher than those of group A from the 8th to the 20th day. Some differences were noticed in the counts of enterococci and lactobacilli in different groups, but they were less consistent.

It is suggested that penicillin stimulates chick growth by causing an increase in feed consumption early in the life of the bird, and that this is associated with an increase in the "coliform" count in the droppings.—K. J. Carpenter.

3967

JACOBS, R. L., ELAM, J. F., ANDERSON, G. W., GEE, L. L., FOWLER, J. and COUCH, J. R.
Further evidence as to the possible mechanism involved in the growth-promoting responses obtained from antibiotics. *J. Nutrition*, 1953, **51**, 507-513. [Dept. Biochem., Texas Agric. and Mech. Coll. System, College Station.]

A group of 25 chicks kept from day-old to 10 weeks in a wire-screen cage in a scrupulously clean room, and fed on a ration of soya bean meal 35, minerals 4, vitamins and yellow maize meal to 100, finished with a mean liveweight of 1200 g. Two further groups received similar treatment with the addition to their ration of either 4.4 p.p.m. penicillin or 11 p.p.m. chloromycetin. The final

weights of these groups did not differ significantly from that of the first group.

In a second trial under similar conditions, the following antibiotic supplements were used (with the concentrations in p.p.m. in parenthesis): penicillin (4.4, 11, 110), erythromycin (4.4), bacitracin (11), aureomycin (11), penicillin (1.1) plus bacitracin (2.75) plus aureomycin (2.75) plus terramycin (2.75), furazolidone (55), furazolidone (28) plus penicillin (2.2), *p*-chlorophenylarsonic acid (100), and *p*-chlorophenylarsonic acid (50) plus penicillin (2.2). None of the groups receiving any of these supplements was significantly heavier than the control group, which again finished with a mean weight of 1200 g.

Estimations of the number of clostridial organisms in the faeces of the different groups were made by a technique used in earlier trials (Abst. 5289, Vol. 23). In the present experiments the mean concentrations per g. of faeces ranged from 400 to 2900 for the different groups, and differences were not significant. In the earlier trials, where antibiotics had stimulated growth, the control birds had given faecal concentrations of 46,000, and the supplemented birds of 12,000 clostridia per g. It is suggested that the antibiotics act by reducing the harmful effects of clostridia when these are present in the alimentary tract in high concentrations.—K. J. Carpenter.

3968

FANGAUF, R., FANGAUF, K. W. and BARLÖWEN, G. v.
 Untersuchungen über den Bedarf an tierischem Eiweiss und den Einfluss der Antibiotika auf das Wachstum der Eintagsküken. [Requirement of animal protein, and the effect of antibiotics on the growth, of day-old chicks.] *Arch. Geflügelk.*, 1954, **18**, 49-65. [Versuchsanst. Kleintierzucht, Kiel, Steenbek.] English summary.

Seven experiments with groups of day-old chicks lasting 8 weeks each are reported. In all experiments the control groups received a ration containing 8 per cent. fishmeal and 8 per cent. soya bean meal. In other groups the amount of fishmeal was reduced and the protein content kept constant by altering the amount of soya bean meal. Some groups received in addition 10 mg. penicillin, streptomycin or terramycin with or without 26 µg. vitamin B₁₂ per kg. feed.

In the absence of antibiotics and vitamin B₁₂ the chicks required 4 to 6 per cent. fishmeal in the ration for optimum growth and feed utilisation. With a supplement of antibiotic and vitamin B₁₂, 2 per cent. fishmeal sufficed. When fishmeal was entirely omitted optimum growth was not obtained even with the antibiotic and vitamin supplements. Antibiotics stimulated the growth of the chicks and their feed utilisation even with

rations containing 8 per cent. fishmeal. In one experiment with penicillin, 6 mg. per kg. of basal ration gave better growth and feed utilisation than 3 mg. Levels of terramycin up to 300 mg. per kg. had no harmful effect on growth.—W. Godden.

3969

CUTHBERTSON, W. F. J. and GLASSER, H. **The use of procaine penicillin in the production of table poultry under practical conditions in the United Kingdom.** *J. Sci. Food Agric.*, 1954, **5**, 153-156. [Glaxo Laboratories, Ltd., Greenford, Middlesex.]

Two experiments were made, with 1107 day-old Brown Leghorn \times Light Sussex and 2100 day-old Rhode Island Red \times Light Sussex cockerels. In each, half of the birds received an unsupplemented basal ration and the rest were given 5 g. procaine penicillin per ton feed. In the first test chicks were weighed at 7 and 15 weeks of age and in the second at 3 and 7 weeks and also when sold at 16 to 18 weeks.

In the first experiment the total yield of table poultry at 15 weeks of age was 2308 lb. from 549 chicks given the basal ration alone and 2605 lb. from 558 chicks given penicillin. The increase in yield, about 11 per cent., was attributable to improved growth and to the lower number of culls.

In the second experiment the total yield in the unsupplemented group was 4521 lb. and in the penicillin group 4822 lb., both from 1050 birds. The birds reached the required weight, $5\frac{1}{2}$ to $5\frac{1}{2}$ lb., in 15.8 weeks when given penicillin and in 17.3 weeks without supplement.

Statistical analysis of the data showed that the gains were highly significant and are summarised by the statement that growth improved by 8.6 per cent. (fiducial range 6.2 to 11.0 per cent., $P = 0.95$), and average cull rate fell by 6.3 per cent. (fiducial range 2.76 to 9.52 per cent., $P = 0.95$), giving a total increase in output in a given time of 15.4 per cent. (fiducial range 11.3 to 19.7 per cent., $P = 0.95$).—P. C. Jowsey.

3970

MEHNER, A. **Aufzucht auf Tiefstreu. [Rearing on deep litter.]** *Arch. Geflügelk.*, 1954, **18**, 12-21. [Inst. Tierzucht., Landw. Hochsch., Hohenheim.] English summary.

In continuation of earlier work (Abst. 1114, Vol. 23), 4 further experiments, each lasting 8 weeks, are reported in which groups of birds were reared on deep old poultry manure, a mixture of equal parts of old poultry manure and cow manure,

or normal deep litter. It was found to be possible to use old poultry manure as litter and get good liveweight gain and feed utilisation and as low a mortality rate among the chicks as on normal litter. There was some evidence of better liveweight increase and lower mortality on manure that had been stored for up to 2 years, and a lower incidence of coccidiosis.—W. Godden.

3971

FANGAUF, R. and BARLÖWEN, G. v. **Wachstumseffekt bei Nitrofurazon-Gaben. [Effect of Nitrofurazone on growth.]** *Arch. Geflügelk.*, 1954, **18**, 29-32. [Lehranst. Kleintierzucht, Kiel, Steenbek.] English summary.

Nitrofurazone mixed at the rate of 0.00625 per cent. in the feed of day-old chickens increased the growth rate over a period of 8 weeks, provided vitamin B₁₂ was present in the diet. The effect was more marked when animal protein was reduced in or removed from the diet. The drug may be regarded as a preventive of coccidiosis with a growth-promoting effect.—W. Godden.

EGG PRODUCTION

3973

MACINTYRE, T. M. and JENKINS, M. H. **A study of the effect of the fineness of grinding grains on the efficiency of all-mash rations for laying hens.** *Canad. J. Agric. Sci.*, 1954, **34**, 10-17. [Dominion Exp. Farm, Nappan, N.S.]

Three all-mash rations of the same composition but ground to 3 different degrees of fineness were given to groups of Barred Plymouth Rock hens housed in pens or batteries. Weight gains, egg production and weights, feed consumption and feed efficiencies were estimated.

The only difference noted was that hens given finely ground mash ate less and had better efficiencies of feed conversion.

When presented with a choice between the 3 rations, the hens showed a preference for coarsely ground feed.—P. C. Jowsey.

OTHER BIRDS

3974

POSPELOV, S. M. O pitanii i khozyaistvennom znachenii sinits, pishchukhi i malogo pestrogo dyatla. [The nutrition and economic importance of *Parus* spp., *Aegithalos caudatus*, *Certhia familiaris* and *Dendrocopos minor*.] *Zool. Zh.*, 1953, 32, 283-287. [Kaf. Lesn. Entomol., Lesotekh. Akad. Im. C.M. Kirova.]

The survey on these birds was made over a period of 2 years in the Leningrad district. The number of stomachs examined ranged from 38 for *Parus atricapillus*, L. to 3 for *Dendrocopos minor*, L. A detailed account is given, but particular attention was paid in the analysis to the presence of insects and their larvae harmful from the silvicultural point of view, which for the 5 species listed amounted to 60, 27.5, 93.6, 75 and 13.6 per cent., respectively, of the total.—D. W. Taylor.

3975

KUMARI, A. R. Pitanie zolotistoi rzhanki i znachenie ee v usloviyakh lesnoi zony rasprostraneniya. [The nutrition of *Pluvialis apricarius* and its importance in the conditions of expansion in forest regions.] *Zool. Zh.*, 1953, 32, 288-293. [Inst. Biol., Akad. Nauk Estonsk. S.S.R.]

An analysis was made of the stomach contents of 80 specimens of *Pluvialis apricarius* (Golden plover) inhabiting the marshy country of western Estonia and its environs. The diet consisted mainly of Coleoptera, Lepidoptera harmful to crops, and in particular of *Plateumaris sericea*, *Sericus brumeus* and *Corymbites sjaelandicus*, and the larvae of the last 2 species.

3976

BOSWORTH, T. J. Control of livestock diseases in Britain: some reflections on the present situation. *Proc. Roy. Soc. Med.*, 1954, 47, 23-26.

The present situation in control of scheduled diseases and programmes for the eradication of non-scheduled diseases is described. Though progress is being made, e.g., in the establishment of tuberculin-free herds, now representing 42.5 per cent. of our cattle population, "the losses caused by livestock disease in the United Kingdom have been estimated at £80 million per annum or about 15 per cent. of the total livestock of the country". We cannot afford this. More should be spent on research, and some reorganisation is necessary for the acquisition of new, and the application of existing, knowledge.—T. D. Bell.

USUELLI, F. Produzioni agrarie e zootecniche e situazione demografica. [Agricultural and animal production and the demographic situation.] *Riv. Zootec.*, 1954, 27, 33-37; 75-80.

The problem of the pressure of growing population in a world already overpopulated in relation to its capacity to produce food is discussed. Erosion, caused by the rapacity of man, is blamed for the unproductive state of a large part of the earth's surface, and in spite of the great progress

already made, the scientist cannot, within the foreseeable future, be expected to satisfy our needs with synthetic foods. For the present we must depend on agriculture and apply our existing knowledge to make ends meet.

The situation outside Europe, in Russia, the rest of Asia and Australia is outlined. Neither South and Central nor North America can hold out hopes for the future. In the former overpopulation already exists, and particularly in Central America the land is still being robbed. In North America, in spite of enormous production at present, the future is menaced by the rate of erosion. In general the answer to the problem is in recognition of the fact that we must co-operate with nature and maintain and improve agricultural production.

The outlook in Italy is not good, owing partly to bad distribution of available food. The population is likely to increase and birth control is not effective against this possibility. The answer lies in increased production from the land, care and improvement of plants and stock, and wider consumption of products which are in abundance.

HJELM, L. Lantbrukets lönsamhetsutveckling under efterkrigstiden. [Economics of agriculture since the war.] *Kgl. Lantbruksakad. Tidskr.*, 1953, 92, 333-348. English summary.

In Sweden the total produce of agriculture has increased since 1945 by roughly 10 per cent. This is due chiefly to oilseeds and almost entirely to the continued extension of crop acreages arising from

the elimination of 160,000 horses, and improvement in yields per acre by greater use of fertilisers. The number of cows has been reduced by 250,000, but total milk yield is little changed. Sheep have been reduced to half and pigs have somewhat increased. Mechanisation has greatly increased, so that the return for labour has also increased.

Farm income is analysed in relation to district, size of holding, and type of production. Wages are still below those of industrial workers, but farmers with 10 to 20 hectares or more of land are better off than before.—I. Leitch.

IMPER, A. D. and HAUGHS, M. A. Report on the production of milk 1952–53. Aberdeen and District Milk Marketing Board area. *North of Scotland Coll. Agric., Agric. Econ. Dept. Rep.* No. 27, February 1954, pp. 19.

Forty herds in the Aberdeen, Banff and Kincardineshire area were costed, 24 for the fourth year in succession. Herd average, including dry cows, was 45, range 10 to over 69, and farm size varied

from 49 to 740 acres. Average yield was 842 gal. compared with 814 for 1951–52. Including a herd replacement of 27 per cent., winter production costs were £48 11s. 11d. per cow and 2s. 4d. per gal.; 21½ weeks' summer grazing cost £32 4s. 2d. and 1s. 5½d. per gal., giving an annual average of 1s. 11½d. per gal. Grazing costs were £5 13s. 1d. per acre or 5s. 1d. per cow weekly. Annual costs per cow varied from £60 to £110 and herds with highest yields generally produced milk most cheaply, though they used more purchased foods.

W. Thomson.

3985

CAMBRIDGE UNIVERSITY SCHOOL OF AGRICULTURE, FARM ECONOMICS BRANCH. Profitable milk production. 1. Some problems of milk production on arable farms. *Farmers' Bull.* No. 15, January 1954, pp. 28. Price 2s. 6d.

The present position of the milk producer is discussed and conditions in 1951–52 are compared with those in 1938–39. Though wages increased by 213 per cent. labour cost per gal. had, through greater efficiency, increased by only 146 per cent., and though the cost of purchased concentrates increased by 317 per cent. the actual cost of these per gal. increased by only 83 per cent. owing to the greater use of homegrown foods. In 40 herds the profit per cow at 1938–39 purchasing power was £14 16s. for 1938–39 and £15 16s. for 1951–52. Aspects of costs and profits in relation to herd size, yield and seasonal peak period are discussed. It is concluded that milk on the mixed arable farm is in a relatively less favourable position than formerly, owing to decreasing opportunities for adjustment and more competition from other farming enterprises; and that, since the liquid milk market is now satisfied, further price stimuli can hardly be expected.

DIET IN ETIOLOGY OF DISEASE

GENERAL

3990

- PUNTRIANO, G. O. **Urinary calculi in livestock—a new concept of its etiology and possible prevention with hyaluronidase.** *J. Amer. Vet. Med. Assoc.*, 1954, **124**, 55-62. [State Vet. Lab., Laramie, Wyo.]

Ultramicroscopic studies of the urine of sheep and cattle showed that in both there is a complex of colloids and crystalloids held dispersed in a fluid phase. In healthy subjects, most of the crystalloid structures are coated by accumulations of colloidal material which presumably prevent the growth of the crystals, such colloids being termed hydrophilic or protective. Other urinary colloidal material (hydrophobic) has the property of aggregating into clumps in the presence of electrolyte, if not prevented from doing so by the presence of an adequate concentration of protective colloids; when this is inadequate, not only is protection diminished but the low concentration of hydrophilic colloids actually enhances the clumping tendencies of hydrophobic colloids, thus leading to the opposite of protection, called "sensitisation".

It is postulated that colloid-crystalloid balance may be influenced by such conditions as mineral and fluid intake, and by environmental stresses. In steers affected with urolithiasis, the urine exhibited subnormal colloidal activity and surface tension. It is shown that subcutaneous administration of hyaluronidase to healthy animals not only raised these values, but also reduced urinary turbidity, and this suggests that its continued use (as by subcutaneous pellet implantation) might prove of therapeutic value in urolithiasis, provided that the dose was adequate; inadequate dosage might well be actually harmful, by producing sensitisation.—W. A. Greig.

- BEVERIDGE, W. I. B. and JOHNSTONE, I. L. **Sheath-rot, non-contagious posthitis or chronic ulceration of the prepuce of sheep. 2. Experiments on the reproduction of the disease.** *Austral. Vet. J.*, 1953, **29**, 329-336. [Div. Animal Health Prod., C.S.I.R.O., McMaster Animal Health Lab., Sydney.]

Attempts to transmit sheath-rot, by transferring material from established lesions to the prepuces

of healthy sheep, all failed; nor was it possible to produce the disease by mechanical means such as occlusion of the preputial orifice or local irritation.

From a series of 13 feeding experiments it was found that a high-protein leguminous diet rapidly produced external ulcers, as did a diet low in Ca and high in phosphate; but typical sheath-rot only occasionally ensued. These results are not considered conclusive, but it is held that sheath-rot is mainly dietetic in origin, and that it may result from irritation by urine in which there is ammoniacal fermentation of the nitrogenous constituents. These conditions would be set up by alkaline urine rich in urea following a high-protein leguminous diet.—W. A. Greig.

DEFICIENCY DISEASES

3996

- SENIOR, B. J., SHEEHY, E. J., O'SULLIVAN, G. F. and O'DONOVAN, J. **Blood copper deficiency in Offaly cattle.** *Sci. Proc. Roy. Dublin Soc.*, 1954, **26**, New Ser., 263-273. [Dept. Animal Nutrit., University College, Dublin.]

Poor conditions, scouring and stunting were found in phosphate-deficient areas in Offaly. The affected animals readily responded to ⁵⁹Cu sulphate in solution, although in some cases 3 or 4 drenches were necessary. Blood samples were

taken before treatment, and Cu values were found to be low. On adjacent unaffected farms the values were normal. When the herbage from affected and unaffected farms was analysed there was no significant difference in Cu content, but the Mo content was high on the affected farms.

3997

WOLBACH, S. B. and HEGSTED, D. M. **Perosis: epiphyseal cartilage in choline and manganese deficiencies in the chick.** *Arch. Pathol.*, 1953, **56**, 437-453. [Div. Nutrit. Res., Div. Labs. Res., Child. Hosp., Boston, Mass.]

Groups of chicks were given control, Mn-deficient or choline-deficient diets from 4 days of age. By the 14th day distinctive changes in the epiphyseal cartilages were well established in birds of both deficient groups. Addition of 0.1 per cent. Mn or 0.3 per cent. choline to the diets prevented the occurrence of lesions.

The skeletal lesions were typical of perosis and were exactly similar in both deficiencies, suggesting that Mn and choline meet in a common biochemical system. The changes followed from retardation or suppression of epiphyseal cartilage sequences, so that endochondral bone growth was affected. Changes were profound, beginning with failure of the cartilage cells to reach maturity and followed by retarded tunnelling and an abnormal matrix in the zone of growth. Later changes involved all zones of the cartilage, and included actual reduction of mitoses in the zone of proliferation. There was no apparent interference with osteogenesis, and consequently the columns of cartilage in the endochondral region almost completely disappeared. It is considered that the term perosis should be reserved for skeletal abnormalities involving these distinctive changes in the epiphyseal cartilage.—W. A. Greig.

3998

JOVANOVIĆ, M., PANTIĆ, V. and MARKOVIĆ, B. **[Enzootic goitre of domestic animals in PR Serbia.]** *Acta vet., Belgrade*, 1953, **3**, 31-51. [Inst. Pathol. Physiol., Fac. Vet. Med., Univ. Belgrade.] In Russian: English summary.

In areas where the inhabitants suffer from goitre, hypothyroidism was observed in domestic stock also.

The incidence of enlarged thyroids and the degree of enlargement were greatest among goats, but other signs, such as dwarfism, sterility and low vitality, were not seen, though poor lactation was reported where enlargement was found.

In sheep the enlargement of the thyroid was not so pronounced, but poor lactation and wool production, and high mortality rate in lambs, were noted.

The percentage of enlarged thyroids in cattle was similar to that in sheep, but disorders thought to be due to hypothyroidism were reported, including poor condition of young stock, and sterility, poor milk yield, short lactation, and too frequent silent heats in cows.

Among pigs little abnormality was seen, but pig-breeding is not highly developed in this area.

Goitre occurred also in horses, less in foals than adults, and though the more primitive breeds showed a higher incidence, imported thoroughbred stallions seemed to suffer more than homebred. Affected animals were less able to work, and stallions had decreased sexual impulse. In affected foals general condition was good while they were young, but they did not develop normally, and were often stunted.

Goitre has been reported also in dogs. (From summary.)—T. D. Bell.

DISEASES OF METABOLISM

3999

BARTLETT, S., BROWN, B. B., FOOT, A. S., ROWLAND, S. J., ALLCROFT, R. and PARR, W. H. **The influence of fertiliser treatment of grass-land on the incidence of hypomagnesaemia in milking cows.** *Brit. Vet. J.*, 1954, **110**, 3-19. [Nat. Inst. Res. Dairying, Shinfield, Reading.]

In April 1952, 22 milking cows were turned out directly from winter feeding to a superphosphate-dressed sward of cocksfoot and clover, divided into 3 plots. Plot A had been treated with magnesite and sulphate of ammonia, plot B with sulphate of ammonia alone, and plot C with sulphate of potash. The animals were watched for a few weeks and samples of blood were taken at least twice weekly for Mg and Ca estimations. Samples of the herbage on each plot also were chemically analysed.

The following year a similar procedure was adopted with 20 cows. The whole field had received more superphosphate, and in addition plot A had received more sulphate of ammonia but not more magnesite. Plot B had been split into B₁, treated this year like plot A, and B₂, which received no further dressing. Plot C had received more potash and the dominant clover had been suppressed with a hormonal spray.

Taking the 2 years together, none of the 9 cows on plot A showed signs of grass tetany and only 1 showed a substantial drop in serum Mg. Of 15 cows on plots B (1952) and B₁ (1953) 11 had very low serum Mg levels, and, of these, 2 died suddenly and 5 others developed typical grass tetany. In 4 others given supplementary concentrates the serum Mg did not fall so low. On plot B₂ (1953), the serum Mg of the 4 cows remained

N.A. and R., July 1954

at or near normal levels, as did that of the 4 cows on plot C in 1952. But in 1953, in 3 of 4 cows on plot C (with less Mg-rich clover) serum Mg fell to low levels. In general, all serum Ca values remained in the normal range, although in most animals showing signs of grass tetany serum Ca fell 2 or 3 days earlier.

The nitrogenous fertiliser increased the crude protein content of the herbage, and the Mg content of the herbage on the magnesite-treated plot was substantially higher than that from the other plots, especially in the second year. Nevertheless, the Mg content of the sward on all plots was more than adequate by accepted standards.

In these experiments low serum Mg was found almost exclusively where the sward contained little clover, and, although clover contains more Mg than does grass, the lack of direct correlation between serum Mg and the Mg content of the sward suggested that there may well be some complication and that the disease results from dysfunction of the physiological mechanism controlling serum Mg, not from direct dietary deficiency; by boosting the daily Mg intake to high levels, however, frank disorder can be prevented.

W. A. Greig.

McAULIFF, J. L., PHILLIPS, W. V. and STEELE, J. R. **Treatment of ketosis in dairy cattle: a clinical report.** *Vet. Med.*, 1954, **49**, 69-74; 88. [Armour Vet. Labs., Chicago, Ill.]

Over a period of a year, 45 cows in New York State diagnosed as affected with ketosis, the criteria being clinical evidence with blood sugar less than 40 mg. per cent. and blood ketones more than 10 mg. per cent., were treated with Adrenomone, a proprietary product prepared by Armour Veterinary Laboratories. This form of treatment was instituted on the supposition that ketosis involves derangement of the pituitary-adrenal balance. In some animals ketosis was complicated by other disorders, but the degree of success achieved was judged by the ketone content of the urine and, in some, by blood sugar and ketone levels.

Of the 45 cows, 30 recovered, 13 improved and the remaining 2 gave good responses. Only 8 animals required continuation of treatment beyond the third day.—W. A. Greig.

POISONS OCCURRING IN FOOD

4001

NAFTALIN, J. M. and CUSHNIE, G. H. **Pathology of bracken poisoning in cattle.** *J. Comp. Pathol.*, 1954, **64**, 54-74. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Vol. 24, No. 3

A diet containing 60 per cent. dried bracken was given to 8 heifers; for 4 of them the ration was made up with 40 per cent. hay, and for the other 4 with 20 per cent. hay and 20 per cent. molasses. Four control heifers received 60 per cent. grass and 40 per cent. hay. A further 3 heifers were given 60 per cent. sun-dried bracken and 40 per cent. hay for 9 weeks and were then offered fresh bracken only. To one of these a complete vitamin B supplement was daily administered subcutaneously; to the second 50 mg. vitamin B₁₂ was given daily for about 12 weeks, followed by amounts up to 250 mg. twice daily. The third heifer received no vitamin supplement.

All the animals fed on bracken lost condition and died in from 38 to 92 days, the control heifers remaining well. Neither the molasses nor the vitamin supplements influenced the course of the disease or the post-mortem findings.

Early signs of the disease were the appearance of large numbers of squamous epithelial cells in the urine, followed shortly by blood. In one animal these signs appeared after only 6½ weeks. Heart beats slowed to 40 or 50 per min., often within a week or two of the commencement of bracken feeding, but rose sharply a few days before death. At this time rectal temperature, which had remained within normal limits until then, rose to 105° to 107° F., the rise coinciding with the development of a non-specific bacteraemia. Body-weight was maintained on the dried bracken diets, but diminished when fresh bracken was introduced.

The main haematological finding was progressive diminution in the number of circulating white cells and platelets. In the terminal stages the leucocyte count dropped to about 1000 cells per c.mm., all of them lymphocytes. When the platelet count fell below 40,000 per c.mm. the clot failed to retract.

Post-mortem examination revealed multiple haemorrhages throughout the carcase. Their degree and exact location varied from animal to animal, but the tissues affected included the subcutaneous tissues, fascial planes, muscles, serosae, subserosae, mucosae and submucosae. Organs affected included the rumen and the whole of the alimentary tract, the liver, gall-bladder, spleen, kidneys, ureters and bladder, heart and lungs. Histologically the haemorrhages were either associated with bacterial infarcts (liver, kidney, lung, spleen and muscle) or were perivascular as in thrombocytopenia (alimentary and urinary tracts). The bone marrow was pale, with a large decrease in cell numbers. Myeloid cells and megakaryocytes were almost completely absent, with erythroid cells also, though less severely, diminished.

It is concluded that the essential lesion in bracken poisoning is bone marrow damage leading to a diminution in the numbers of circulating

platelets and granulocytes. Subsequently there are multiple haemorrhages and bacterial invasion of the bloodstream. The cause of the bone marrow damage remains obscure, but it is suggested that the damage may result from depletion of some substance synthesised by the micro-organisms in the rumen, or from a toxic material either in bracken itself or formed by these micro-organisms as the result of altered metabolism.—W. A. Greig.

4002

NAFTALIN, J. M. and CUSHNIE, G. H. **Experimental bracken poisoning in calves.** *J. Comp. Pathol.*, 1954, **64**, 75-86. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Five calves aged from 62 to 105 days were fed on either fresh or dried bracken. A sixth calf fed on grass was studied as a control. Three of the bracken-fed calves developed the typical syndrome of bracken poisoning after 29 to 37 days. The lesions were identical to those in adult animals (preceding Abst.), the most primitive myeloid and erythroid cells in bone marrow being those most affected. Once formed, mature polymorphs appeared to be unaffected.

The other 2 bracken-fed calves died suddenly from heart failure on the 23rd and 29th days without rise in temperature or haemorrhage, but they also had severe bone marrow damage. One of these had been given 250 mg. vitamin B₁ twice daily by mouth from the beginning of the experiment.

It is concluded that the typical syndrome of bracken poisoning in the adult also develops in calves given bracken, if they live long enough.

WHITTEN, L. K. and MACFARLANE, I. M. **The effect of monthly anthelmintic treatment on the growth of young sheep rotationally grazed on hill pastures.** *N.Z. Vet. J.*, 1953, **1**, 150-153. [Dept. Parasitol., Wallaceville Animal Res. Stat., Palmerston North.]

Observations on the weight gains and helminth egg counts of 150 weaned lambs on rotational grazing are described. The paddocks were rested for 3 to 4 weeks before they were grazed again. There were 3 groups of 50 lambs which were grazed together. Group A received 20 g. phenothiazine per lamb at monthly intervals; group B received 28 ml. of 2 per cent. copper sulphate and nicotine sulphate per lamb at monthly intervals; group C was untreated. Groups A and B showed significantly better weight gains than the control group and group A showed better weight gains than group B.

The egg counts of the control group rose rapidly in February and March, maintained a high level in April and May and fell in June. Group B showed a similar but much smaller rise starting in March. Group A maintained a low level without any significant rise.—G. C. Hunter.

WUHRMANN, F. and WUNDERLY, C. **Die Bluteiweisskörper des Menschen. [The blood proteins of man.]** Benno Schwabe and Co. Verlag, Basle, 1952, pp. 387. Geb. Fr. 42.

This book is a second edition, largely rewritten, of a monograph first published in 1947. The first chapter of 50 pages is a survey of the chemistry and physiology of the plasma proteins. This is followed by sections on the qualitative and quantitative estimation of proteins in general and the fractionation of plasma proteins in particular. The clinical laboratory techniques related to plasma proteins are discussed and described in great detail. This covers, with many other tests, the Takata reaction, the thymol turbidity test, and related reactions. The main part of the book (over 200 pages) deals with the clinical significance of plasma protein analysis and plasma protein reactions.

The authors draw on extensive personal experiences and have provided a very comprehensive and competent survey of the field. There are full

references to original papers, reviews and monographs. The presentation tends to be lacking in conciseness but this is a minor point. The book is without doubt a most valuable and unique source of information.—H. A. Krebs.

4014

BACH, S. J. **The metabolism of protein constituents in the mammalian body.** The Clarendon Press, Oxford, 1952, pp. viii + 272. Price 40s. [Dept. Physiol., Univ. Bristol.]

The past decade has seen a very rapid development of the knowledge of amino-acid metabolism. A monograph collecting and sifting the mass of information is therefore very timely. The present volume deals with the biochemistry of alanine, glycine, serine, threonine, valine, leucine, *iso*-leucine, cystine and cysteine, and methionine; a second volume is planned to cover the remaining protein constituents. The treatment is limited to the purely biochemical aspects. The organic chemistry of amino-acids is rightly omitted.

The author has made an exhaustive and critical study of the literature and condensed in this book a large volume of widely scattered information. All ramifications of the metabolism of individual amino-acids are dealt with. The chapter on glycine alone, for example, covers 61 pages and includes a detailed discussion of the synthesis of hippuric acid, nicotinuric acid, porphyrins, uric acid, bile salts, creatine and serine. More than half the book is occupied by the sulphur-bearing amino-acids.

It is a special merit of the book that the historical development of the subject is very adequately presented. The monograph will prove invaluable to advanced students and to workers in the field.

4015

BENNETT, M. K. **The world's food. A study of the interrelations of world populations, national diets, and food potentials.** Harper and Brothers, New York, 1954, pp. vi + 282.

In chapter 1 of this book the "terrifying" picture is drawn of population growth as it might have been if man had ever reproduced to full capacity. The important upsurge of population dates from about 1650 and economic advancement, which connotes sanitation, warmth, drugs, transport and, possibly, improvement of man's morals, has provided the lift. Chapter 2 reviews rapidly and brightly the dispersion of man and foods over the earth and the history of diet, with the suggestion, only half apologised for, that the upsurge of population in the seventeenth century could not

have occurred without the dispersal of American food plants to the rest of the world. There is a vivid sketch of the shocks of weather and plagues of insects and the European famine of 1315. The third chapter discusses Malthus and the neo-Malthusian in the sensible light that "arithmetic carries in itself no element of prediction, no element of compulsion". Society can, if it will, choose what birth rates and food supplies it will have, if it also chooses to avoid war and economic autarky.

Part 2, chapters 4 to 11, is occupied with a semi-technical and economic account of the American national diet. Part 3, with 5 chapters, reverts to subjects of more general interest; world geography of hunger, the relation of consumption to income, and food in war time.

FAO is thought to overassess "hunger", even if hunger be interpreted to include lack of the full measure of any one of the known essential components of diet. Of those roughly classified as "hungry", most "may be quite unconscious of living an abnormal existence". Certainly this is true. Underemployment in agriculture and low activity connote low food intake; the extremely poor or the primitive do not recognise deficiency disease as such. But unconsciousness of these admitted abnormalities does not justify our indifference to them. FAO judges hunger, not in relation to existing states only, but in relation to such improvement as is agreed to be desirable. FAO, in the guise of an "inspired leader", is counselled to seek confirmation on medical grounds for the association of malnutrition with poverty and relative lack of foods other than starchy staples. But this is almost the *pons asinorum* of nutrition theorems and WHO, no less than FAO, has accepted it. On occasion it seems to be forgotten that FAO works with estimates of food supplies made by the supporting countries of which some do little more than provide an incentive to improve.

The whole treatment of the subject is intelligent and critical. No one will question that the "peasant logic which calls for submission to adversity if it comes, not for anticipatory outlay of effort when nobody knows whether adversity will or will not come" exists. I suppose it will always be an impediment to progress, and not only among peasants. It is also, in its own way, a safeguard. The general thesis, in spite of the criticism, is in accord with the principles on which FAO was founded and now works. There are many details that could be argued, and many arguments that could be debated at length. The book is provocative and perhaps therefore all the more valuable when so many books on the same subject are only dull or irritating. Teachers of nutrition should greatly welcome it.—I. Leitch.

4016

FINNEY, D. J. **An introduction to statistical science in agriculture.** Oliver and Boyd, Edinburgh, 1953, pp. 179. Price 25s.

The preface states that this book has grown from a course of 8 lectures given to agricultural students at Oxford. It is to such that it is directed, and in its aim to show the foundations of statistical science and its application to agricultural problems, it contains a minimum of mathematics. Many worked examples are included, but their intention is to illustrate the principles rather than to act as a guide to computational methods.

There are 9 chapters dealing with probability, distributions and their uses, design, sampling, regression and correlation. Included amongst these is a most instructive chapter describing in detail the steps taken in conducting a simple experiment. Finally, a valediction containing some simple and sensible rules is included. If these were distributed to all workers about to embark on an experiment they might well save many post-operative pains.

In fine, the book achieves its stated intentions admirably, and should be available to every agricultural student, if not on his bookshelf on account of its high price.—A. W. Boyne.

SEN, K. C. **Animal nutrition research in India.** Macmillan and Co., Ltd., Calcutta, 1953, pp. xii + 370. Price 25s.

This is one of a series of critical monographs to be published under the auspices of the Indian Council of Agricultural Research in which it is designed to set forth the results obtained by Indian workers and to compare them with the results of workers in the same fields in other countries.

The present review opens with a short chapter giving an outline of agriculture and animal husbandry in India. There follow chapters dealing with the composition, digestibility and nutritive value of Indian feedingstuffs, conservation of fodders, poisonous plants and the effects of vitamin and other deficiency diseases. The animals mainly studied have been cattle or buffaloes, although there are brief references to work with sheep and goats. It is appropriate, therefore, that the last and longest chapter should be devoted to investigations in dairy science concerned mostly with cow or buffalo milk, its composition, handling and processing, and the nutritive value of the milk and its products. The discussions are amply illustrated by tables and graphs of experimental results and at the end of each chapter a full bibliography is given. The author states that he has used his discretion in selecting topics of research for inclusion but, nevertheless, the book furnishes a good

N.A. and R., July 1954

picture of the progress of nutritional research as related to animals in India in recent years.

4018

DAVIDSON, H. R. **The production and marketing of pigs.** Longmans, Green and Co., London, 1953, 2nd ed., pp. xvi + 537. Price 40s.

The first edition of this book was reviewed in Abst. 1642, Vol. 19. For the second edition some details in the text have been revised, but there is no change in the general presentation, which covers in considerable detail every aspect of pigkeeping. Some recent developments in nutrition have been summarised in a short addendum to the text.

Such a wealth of useful and accurate information has been included in this book that the reader can criticise it only where his opinions differ from those of the author. This will undoubtedly occur sometimes, for pigkeeping is not an exact science.

Three of the few omissions of detail in the book are the value of sodium fluoride as an anthelmintic, the use of dry vitamin A and D supplements as an alternative to cod liver oil, and the possibility that there is not quite enough riboflavin in many farm-mixed rations. Some pig farmers might like more information on castration within a few weeks of birth, a practice which is becoming increasingly popular, and many will consider that Mr. Davidson's brief mention of fattening houses with indoor pens and outside runs of the types developed in Ireland and at the Harper Adams Agricultural College is inadequate.

The addendum deals with the animal-protein factor and antibiotics. Mr. Davidson has wisely added a note of caution on the use of antibiotics, for their mode of operation as growth stimulants is not fully understood and we have yet to learn more of their usefulness under the diverse conditions encountered in British agriculture.

Development Paper No. 42. Co-operative hybrid maize tests in European and Mediterranean countries—1952. Rome, Italy, March 1954, pp. v + 179. Price \$2.00. (Cf. Title, p. 251, Vol. 24.)

Development Paper No. 43. Water laws in Moslem countries. Rome, Italy, March 1954, pp. iv + 202. Price \$2.00.

Nutritional Studies No. 11. Food composition tables—minerals and vitamins. Rome, Italy, March 1954, pp. v + 117. Price \$1.00.

These tables are in amplification of those on proximate constituents published in 1949 (see p. 502, Vol. 19). They include data on calcium and iron and on vitamin A and B₁, riboflavin, nicotinic acid and ascorbic acid and an

Vol. 24, No. 3

extensive bibliography with 539 references is appended. In her introductory notes the compiler, Miss C. Chatfield, says that geographical differences as between countries may, in the past, have been overemphasised and that differences caused by variations in season, variety, condition of samples and laboratory practices may be of greater significance. The need for further information where it exists is indicated.

Nutritional Studies No. 12. Rice enrichment in the Philippines. Rome, Italy, March 1954, pp. v + 109. Price \$1.00.

The results obtained during the experimental period of the Rice Enrichment Programme in the Philippines have been described in earlier reports (see Absts. 4905, Vol. 18; 5395, Vol. 19; 2621 and 5683, Vol. 20 and 928, Vol. 21). Early in 1951 enriched rice was introduced commercially throughout Bataan Province and when, in the next year, its issue was extended to Tarlac Province the total population affected was over 400,000. In 1952 a team of experts visited the area and in addition to making a rapid dietary and clinical survey have now reported on the working of the scheme.

Their report is in two main sections which describe rice enrichment in its nutritional and its commercial and administrative aspects. The 17 appendixes include tables which refer to such subjects as relevant work from the earlier surveys, the results of this later one, mortality rates from beriberi and the composition and cost of manufacture of the premix used for enriching rice.

After it had been prepared the report was read by Dr. Juan Salcedo (Jr.) who had been closely connected with the development of the scheme and his views and comments made in his official capacity as Secretary for Health to the Republic are included together with a copy of the Act which regulates the sale of rice.

The problems encountered in the education of a population in the use of enriched rice and in the importation of the chemicals, their addition during milling and its administrative control are considered in full. The experience obtained by the Government of the Philippines in this pioneering work will be of value to other governments contemplating similar action.

Growing food for a growing world. The work of FAO 1952/53. Rome, Italy, February 1954. Price \$0.50.

This report is for the year which ends the first decade since the Hot Springs Conference was held. The need for greater food production is emphasised by the Director-General in his foreword for, although a remarkable increase has taken place during that period, it has occurred in the more developed countries and among the people who are, in the main, already well fed; among the less

fortunate of the world's inhabitants there have been increases in their numbers and in their awareness of their disadvantages. The report provides only a brief summary of the work of the agency. Its efforts are described which aim to extend the world's farm lands, to obtain greater yields from them and to increase their stock-carrying capacities, to improve livestock of all kinds and fishery resources by breeding, better husbandry and the eradication of disease and, towards the end of the scale, to improve methods of marketing the products. Finally the difficult task of educating the populations in making the best use of the foods which reach them is also being tackled. The numerous illustrations give good indication of the variety of the agency's work.

Report of the 7th Session of the Conference, 23 November-11 December 1953. Rome, Italy, March 1954, pp. xiv + 256.

The conference adopted 77 resolutions. Food production in countries excluding USSR, Eastern Europe and China was about 23 per cent. larger than before the war and had, for the first time, caught up with the growth of population. But it was very uneven and 17 of the resolutions were concerned with the trends and policies in respect of food and agriculture. The Organization's work on nutrition came under review and a resolution referring particularly to protein deficiency of mothers and children and recommending the intensification of the work and its co-ordination with that of WHO and UNICEF was approved.

INTRODUCTION

AUSTRALIA is the smallest and least populous of the continents, there being but 9 million people in its 3 million square miles. The United States, with the same area, had a population of 150 million in 1950. Australia has also had much the shortest agricultural history, for the scanty aboriginal population was entirely nomadic, without any agricultural or pastoral industries whatsoever. The commencement of white settlement in 1788, predominantly as a penal settlement, proved somewhat unfavourable for the encouragement of systematic primary production. With the exception of a few significant events, such as the early introduction of the merino sheep and the colonisation of South Australia by free settlers under the Wakefield Scheme, which began in 1836, there was little evidence until transportation of convicts ceased in the middle of the century that considered policies of settlement and land development were being followed.

Hence it is true to say that what has been achieved in Australia is the work of only one century. When the shortness of the time, the unfamiliar and discouraging climatic conditions, the poor soils and the limited water resources of the continent are taken into account, it is indeed surprising that so many Australian people not only support themselves on a high standard of living,

but also contribute materially to the food and clothing supplies of many other lands. Further, the adaptation by trial and error of European agriculture and stock husbandry to Australian conditions in the early years, and the scientific elaboration of farming practices in the last thirty years or so, have proved of widespread interest to agricultural scientists in other regions. It now remains to be seen how far present-day progress can be pushed before forbidding natural conditions prove too difficult for the methods of scientific and economic agriculture.

SUMMARY OF PRODUCTION STATISTICS

Primary production in Australia is characterised by a high degree of mechanisation and large-scale operations. As a result the number of people associated with farming and pastoral pursuits is only 3 million.* The remainder of the population is occupied in secondary and tertiary industries predominantly associated with large cities on the seaboard: the populations of Sydney and Melbourne alone total 3 million people.

The following details epitomise primary production in Australia today and indicate the relative

* Yet this proportion is well above that in the United States, which is approximately one-fifth.

importance of internal and export markets for the goods produced. There are about 115 million sheep, which produce 300,000 tons of meat and 1100 million pounds of wool per annum. Only a small part of the meat is exported, but most of the wool goes overseas. A beef cattle population of almost 10 million produces 700,000 tons of meat annually, of which about one-fourth is exported. There are about 3 million dairy cows in Australia, yielding 1200 million gallons of milk annually. Some of the milk goes to manufacture 165,000 tons of butter and 45,000 tons of cheese, and about half of each is exported. Over 100,000 tons of eggs are produced yearly and one-quarter is exported.

Australia produces 150 to 200 million bushels of wheat per annum from 11 to 14 million acres of crop: about half is exported. Oats, maize, barley, rice, sorghum and peas also are grown, and a proportion of them is exported. Almost one million tons of sugar are produced each year from about 400,000 acres on the eastern tropical and sub-tropical coast. About one-half is exported as sugar and in processed goods. Numerous varieties of both temperate and tropical fruits are produced, in most instances for local consumption, but there is an important export trade in apples and pears, citrus fruits, dried vine fruits and wine, and fruit products such as jam and canned fruit. Production of potatoes and other vegetables is organised to supply the home market, but a small amount of both canned and fresh vegetables is exported.

The agricultural and pastoral production just summarised depends partly on the annual use of 1.5 million tons of artificial fertilisers, chiefly super-phosphate, which are applied to 28 million acres of land, of which half is pasture.

Timber is produced from Australian forests, both natural and planted, to the extent of 1200 million super-feet per annum, of which about 50 million super-feet are exported, but the amount exported is more than counterbalanced by an importation of 250 million super-feet.

PRODUCTION REGIONS

The map shows the broad primary production regions of Australia, in which agricultural, pastoral and forestry practices are dependent on different combinations of types of soil, climate and topography. Each region is discussed here in turn, with reference to established utilisation and to developmental or conservation trends. These regions are naturally somewhat arbitrarily delineated, but so long as some allowance is made for the overlap of primary industries from one region to another they provide a convenient and realistic basis for a discussion of Australian rural activities.

A. SOUTHERN MOUNTAIN REGIONS

There are two of these regions, one in Tasmania and the other on the mainland. The latter embraces the Australian Alps in southern New South Wales and eastern Victoria, and the former the mountainous tracts of the western and southern parts of Tasmania. Elevation ranges from about 2500 to 7000 feet on the mainland and from sea level up to 5000 feet in Tasmania.

The climate is alpine, with from 30 to over 100 inches of precipitation per annum, part of it snow.

The soils consist of high moor peats, alpine humus soils, skeletal soils and bare rock, with podzolic soils in the lower mountain valleys and passes, and peaty podzols on the inter-mountain plains of the region in Tasmania.

The southern mountain regions are used for the sparse summer grazing of sheep and cattle on the rough natural pastures of the highlands. Pasture is being developed as in the temperate regions (B) in the lower valleys and passes, and there is considerable production of timber from natural forests on the lower and intermediate slopes of the mountains.

Above the lower lands very little development appears possible: conservation of soil, vegetation and water resources is of primary concern. All forms of land-use must be subordinated to the conservation of water because hydro-electric schemes are using steadily more, and on the mainland it is required for the irrigated areas in the sub-humid and semi-arid regions (D and E) in south-eastern Australia.

Attempts have been made on an experimental scale to produce sown pastures on the lower lying peaty podzols in Tasmania, but so far the acidity, with pH values down to 3.5, extremely high lime requirement, low fertility and waterlogged nature of these soils have prevented any success of economic significance.

B. TEMPERATE REGIONS

There are four temperate agricultural regions in Australia. The largest, in the south-east of the continent, covers the lower south-east of South Australia, southern and central Victoria, coastal and sub-coastal New South Wales, and a small portion of southern Queensland. The next largest comprises the south-western corner of Western Australia. There is one broken region with the Mount Lofty Ranges, Kangaroo Island and southern Eyre Peninsula in South Australia, and the fourth covers northern and eastern Tasmania and the islands in Bass Strait.

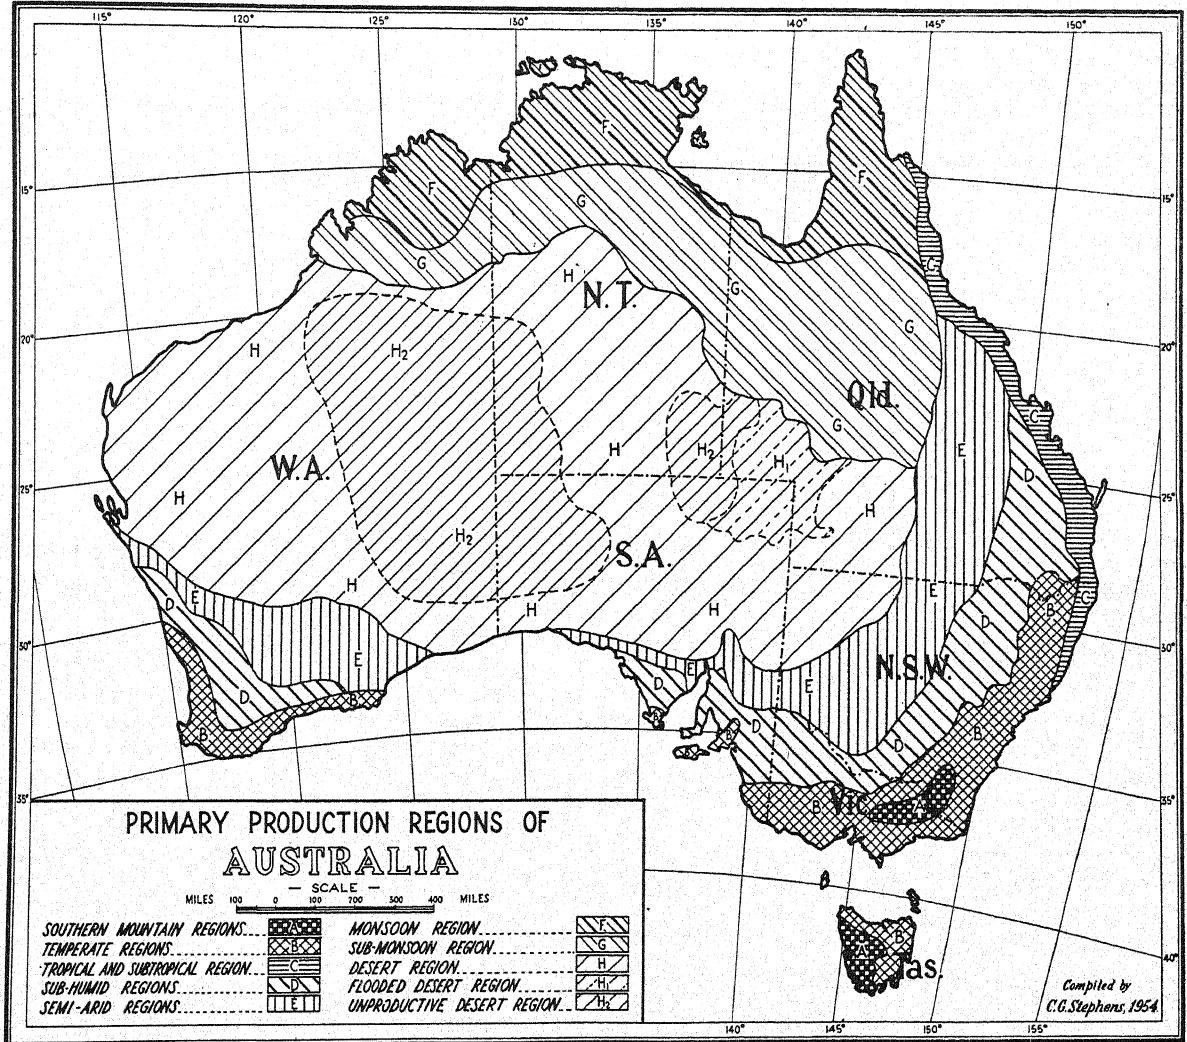

The climate in the temperate regions ranges from mild to warm temperate, annual rainfall being from about 20 to 60 inches, most of it in winter, except in the area in coastal and northern

New South Wales and southern Queensland, where it is more uniformly distributed, with perhaps a slight excess in the summer months.

The soils of the temperate regions consist of a variety of podzolic and solodic soils; lateritic podzolic soils are dominant in the Western Australian region. Skeletal soils are abundant in hilly and mountainous areas and considerably restrict the potentiality of the Tasmanian and

on the podzolic soils. Timber is produced from both native and planted forests, the former dominated by species of *Eucalyptus* and the latter composed principally of *Pinus* spp., of which *P. radiata* is the most extensively planted and productive. There is a trend towards the utilisation of the native forests on a sustained yield basis.

The obvious direction for development is in the further expansion of sown pastures, which has

south-eastern regions. There are small but very important areas of krasnozems, brown earths, rendzinas and alluvial soils.

The predominant land-use characteristic of the temperate regions is stock farming with sheep, and dairy and beef cattle on both native and sown pastures. Farming is mixed on the more fertile soils such as the krasnozems, rendzinas and alluvial soils, and fruit is grown in favourable situations

already been most prominent in agricultural activities in temperate regions for the last thirty years. It dates from the accidental introduction of subterranean clover and the use of superphosphate to top-dress pastures which had subterranean clover or some other legume such as white clover as an important constituent. No particular difficulty has been encountered on the podzolic soils, but on the solodic soils, the lateritic podzolic soils and the podzols

proper, sown pasture was not generally established until deficiencies of trace elements were recognised and corrected. Copper, molybdenum and zinc were involved singly or in combination. Copper, zinc and manganese have proved of importance also for pastures and crops on some of the more fertile soils, such as the rendzinas and black earths in both the temperate and the sub-humid region, and copper and cobalt singly or together have proved to be necessary for the health of stock in some parts of these regions. The early control of coast disease in stock by the use of cobalt and copper has led by the use of one or both of them to control of other defects, such as steely wool, and of a number of animal health disorders of local and scattered distribution, for example, Gould's Country disease in north-eastern Tasmania, and staggers in stock grazing on phalaris-dominant pastures.

The rise in fertility of the soil under top-dressed, sown pastures on the leached soils may well lead ultimately to an expansion of arable farming on to some of these originally poor soils. To meet the needs of soil conservation, arable farming must be restricted to areas of suitable topography, and wide rotations must be used, for these soils will readily lose the structure and fertility acquired under pasture. Of recent years there has been a considerable expansion of potato growing from the long-used krasnozems and swamps on to such soils where they have been many years under pasture, the potato crop frequently being irrigated from small catchment areas on the farm or from locally pumped underground water. In the drier parts of the region winter-sown cereals could similarly make use of the accumulated fertility.

C. TROPICAL AND SUB-TROPICAL REGION

The north coast of New South Wales and almost the whole of the eastward-facing coast of Queensland constitutes the tropical and sub-tropical region. It is a very long narrow area up to fifty miles wide lying between the Dividing Range and the coast.

The climate is tropical in the northern half of the region and sub-tropical in the remainder. Rainfall varies from 30 to over 100 inches per annum, with a conspicuous alternation of relatively dry and wet zones along the length of the region. The areas of higher rainfall arise partly from the juxtaposition of the higher mountain masses and the coastline. There is a notable maximum rainfall in the summer months, and in the drier belts the winter rainfall is so low that irrigation of the sugar cane crop by pumping river or underground water is often standard practice. One such irrigated area on the delta of the Burdekin River has the highest yield of sugar cane per acre in Australia.

The soils of the region are predominantly podzolic but there are more important though smaller areas of krasnozem and alluvial soils and, near Brisbane, lateritic red earths. Solodic soils also are extensive near the coast, where with ground-water podzols and swamps they make up large tracts of relatively open but little used heathland loosely referred to as "wallum" country.

Sugar production stretches throughout the length of the region, but is less intensive in the south. Dairying is much more developed to the south and falls away rapidly even south of the tropic of Capricorn; it is particularly intensive in north coastal New South Wales. Beef cattle are relatively prominent throughout the region. A high proportion, of which many are brought into the area as store stock, are fattened in the area before going to meat works. The beef cattle graze over all types of country, but both dairying and sugar cane production are found chiefly on the better soils such as krasnozems and alluvial soils, with some on podzolic soils.

Production of tropical fruit is extensive in the region, and supplies most Australian requirements. Banana and pineapple cultivation are the most important industries, and are well organised. A significant proportion of the pineapples is canned.

Timber is produced on a moderately large scale in areas of rain forest. Cabinet-making woods and plywood production are important.

The outstanding problem of the tropical and sub-tropical region is the development of sown pastures corresponding in productivity with those of southern Australia where subterranean clover has proved to be a suitable pasture legume. A corresponding clover is needed in the tropics, especially in the more northerly areas and on the poorer podzolic and solodic soils. In the southern portion of the region, white clover occurs in *paspalum* and *kikuyu* pastures on the more fertile soils on which the dairying industry is concentrated. A good deal of effort has so far been devoted to seeking the right plant, with trials more particularly of such wellknown tropical pasture legumes as *Stylosanthes* and *Centrosema*, but so far with only partial success. The full solution will not only extend the dairy potential of the region, but also greatly increase meat production, since at present grazing by beef cattle is confined almost entirely to natural pastures.

Cultivation of sugar cane and tropical fruit has brought soil conservation problems in its train. A great portion of the sugar cane and some tropical fruit, especially bananas, are grown on moderately to strongly sloping land. Although many of the soils in these situations are highly permeable, they are not sufficiently well structured to resist the impact of heavy tropical rain. Consequently sheet and gully erosion are common, and can occur

in certain circumstances even while the land is under a heavy crop of cane. There are a number of contributing circumstances, the most notable of which are the common practice of running cane rows up and down the slope, lack of trash conservation, and restriction of the cane crop, under the assignment system used to control the industry, to specific tracts of land. The last procedure tends to prevent the development of suitable rotations and the adequate use of green manure crops, with consequent damage to soil structure and reduction of permeability. So far no widely used system of soil conservation has been evolved, but such a system will become increasingly imperative as losses of soil and reduced fertility cause yields to decline and so neutralise the splendid efforts of the plant breeders who have produced remarkably high yielding varieties of cane during the last three decades. The situation will ultimately correspond very closely with that in the wheat-producing areas in the sub-humid regions (D) unless appropriate techniques are found for soil conservation. In other parts of the region there is intermittent erosion of alluvial soils by flooding, which causes river banks to collapse and fields to be stripped of their cultivated layer.

D. SUB-HUMID REGIONS

There are two sub-humid regions; the smaller is the agricultural belt of Western Australia and the larger the area extending from Eyre Peninsula in South Australia through north-western Victoria and the western slopes of New South Wales to the southern subcoastal area of Queensland.

The climate is characterised by a clear periodicity of the rainfall, which varies from 12 to 30 inches per annum. In the south and west there is a Mediterranean type of climate with winter rain and summer drought. In northern New South Wales and southern Queensland most of the rain falls in summer, but there are also useful winter rains.

The soils of the eastern region comprise broad sweeps of red-brown earths, black earths, solonised brown soils, grey and brown soils of heavy texture and solonchic soils. The black earths are predominant in Queensland and northern New South Wales. The region in Western Australia is composed of a complex of unidentified brown soils with solonchic and relic lateritic podzolic soils. Skeletal soils are common in parts of the sub-humid regions but nowhere cover large tracts of land.

The sub-humid regions form the wheat and sheep belt of Australia. Arable farming is predominant, and is devoted largely to wheat-growing, mostly on short rotations. Other cereals such as barley and oats are important also, and in the summer-rain areas grain sorghum and maize are common crops, although the last is grown to a larger extent

in the tropical and sub-tropical region. Sheep are grazed on both natural pastures dominated by *Danthonia* and stubbles and volunteer pastures in the wheat-growing rotation; in addition some relatively small areas of lucerne, where conditions for its growth are suitable, are used for sheep grazing, but more important are the sown pastures in the moister parts of the regions. The sown pastures, being based on short-season strains of subterranean clover such as *Bacchus Marsh* and *Dwalganup*, represent a spill-over from the temperate regions, but such pastures are not possible all through the sub-humid regions and in the middle and drier parts a volunteer growth of medicks is the most important legume.

In New South Wales, Victoria and South Australia the sub-humid region, with the adjacent part of the semi-arid region (E) in New South Wales, is the site of the main irrigation works of Australia. It is mostly red-brown earth and solonised brown soils that are irrigated, but there are significant areas of grey and brown soils of heavy texture and lesser areas of swamp soils also irrigated, the former of particular importance in the production of rice. Citrus, vine and stone fruits, and pastures are the principal irrigated crops. The fruit industries, which include dried fruit production on a large scale, are concentrated on irrigated, solonised brown soils and red-brown earths. Irrigated pastures are grazed by both sheep and dairy cattle.

Associated with the industries just described there are a number of problems and developmental possibilities, of which the erosion problem of the wheat lands is probably the most urgent and important. By statistical analysis of the records of wheat yields in the several districts in South Australia, Cornish (1949) has been able to show that after an early initial rise associated with land development, wheat yields are now declining or beginning to decline, or are stabilised over the greater part of the wheat belt in the State, continuing to rise in only a small part of the area. The fall in wheat yields is associated with declining soil fertility due to soil erosion, deterioration of soil structure and loss of organic matter. The writer and his colleagues (Stephens *et al.*, 1945), by the study of a selected area during an extensive soil survey, were able to show that the soil deterioration is associated with a combination of poor management practices, namely, short rotations, frequently two-course, fallow-wheat, and overgrazing by sheep. It is considered that the conditions revealed by these investigations apply in some degree throughout the wheat-growing areas of Australia and that they have largely negated the beneficial effects of the wheat-breeding programmes and the fertility and rotation investigations of the several scientific institutes.

Fortunately a vigorous programme of soil conservation research and extension is now under way throughout most of Australia, but it must be realised that some of the damage is permanent, especially in the areas severely affected by wind erosion and by deep gullying. In Western Australia the problem is complicated by the development of salinity in some of the soils.

At the present time there are about one and a half million acres of irrigated land in Australia. Probably twice that area, perhaps three times, might be irrigated, but beyond that there seems little prospect of further development, because of the limited water supplies. It therefore becomes important to make the best use of the available water; that is, to use it on the most responsive soils, for the most valuable crops, and to minimise loss of water through evaporation and seepage by conveying the water over the shortest possible distances. The sub-humid region of south-eastern Australia offers the best possibilities. There are limited prospects in the temperate regions (B), more particularly in Western Australia, where, however, salinity may cause difficulty in some parts in the future. In eastern Australia some irrigation in the semi-arid region (E) has already been attempted, but an increasing proportion of heavy-textured and slowly permeable soils has already brought significant problems to light. The possibilities of irrigation in north and central Queensland may have to be assessed and tested in terms of such soil conditions, for suitable lighter-textured soils are not common there except as narrow ribbons of levee bank formations.

Pasture development in the sub-humid regions outside, as well as in, the irrigation areas is of particular importance and interest. As was mentioned above, the wheat lands are characterised, between crops, by volunteer pastures in which the medicks play a major role. Some progress has been made in selecting suitable strains, particularly of barrel clover (*Medicago tribuloides*) in which the spines of the seed pod are suppressed, and in demonstrating the value of sowing pastures with this legume as a component, although it is not adapted to all soils and climates within the sub-humid regions. There is a conspicuous need for suitable grasses; in the south annual Wimmera ryegrass under careful management can do much to meet the need.

On the solodic soils of the moister areas a recent success of notable importance is the demonstration by Riceman (1948) that pastures based on the short-season strain of subterranean clover, Bacchus Marsh, can be established provided the minute requirements for the trace elements, zinc and copper, are met and adequate phosphate is supplied. This investigation has led to what is almost a boom in pasture establishment on these

and other equally poor soils by both official and private organisations and by individual landholders.

Another interesting and well organised development in recent years has been the production of groundnuts in the sub-humid region in Queensland, notably around Kingaroy. About 10,000 tons of nuts are now produced annually from 20,000 acres of land.

E. SEMI-ARID REGIONS

The semi-arid regions include two units, the larger, in eastern Australia, covering a portion of South Australia, the central west of New South Wales and the east central part of Queensland. The smaller unit is a belt of variable width in Western Australia stretching from the Great Australian Bight to the west coast.

The climate is semi-arid with an annual rainfall varying in the southern areas from 8 to 15 inches and in Queensland up to 25 inches, the larger figure applying only to the northern extremity of the region, which comes within the range of both the summer monsoonal and the tropical coastal weather system. In the southern areas most of the rain falls in the winter.

There are solonised brown soils, brown soils of light texture, grey and brown soils of heavy texture, and desert loams, with some considerable areas of black earths entering the northern part of the eastern region in Queensland. In some localities there is a relative abundance of skeletal soils.

Predominantly the semi-arid regions are devoted to sheep grazing, but beef cattle are important in the eastern unit and increase in numbers in the Queensland portion. Almost all grazing is on natural pastures, some of which have the character of shrub steppe. *Danthonia* is the important grass in the south and Mitchell grass (*Astrebla* spp.) and other tall species in Queensland.

In the semi-arid part of southern New South Wales there is some irrigation, the principal intention being to provide irrigated pastures capable of producing fodder for conservation and thus exerting some stabilising influence against the depleting effects of periodic droughts on the sheep industry. But, under the difficult conditions of this area, with its fine-textured and slowly permeable soils, the development of irrigated, sown pasture has been beset with difficulties, and as yet is little more than a subject for research and experiment.

Two serious and unfortunate problems are common to the semi-arid regions. The first, closely associated with the grazing industry, particularly in the southern areas, is the prevalence of sheet and "scald" erosion, the latter due to both wind and water scouring. Initially both these forms of erosion are caused by overgrazing, which lays bare

the soil to the forces of wind and water on flat as well as sloping sites. "Scald" erosion occurs mostly on flat or gently sloping land where the eroded surface develops a type of sealing which is particularly unfavourable for seed germination and plant establishment, and is often accompanied by increased soil salinity, an added deterrent to plant re-establishment.

The second problem appeared when attempts were made to extend arable agriculture to the semi-arid regions without benefit of irrigation. In the southern areas such attempts were associated with former campaigns for increased wheat production. Because of the unreliable and insufficient rainfall, and despite the breeding of hardier types of wheat, attempts to grow grain in this area were finally abandoned. The short and unreliable rainfall season provided too little moisture for economic crops and, after some aggregation of farms, most of the land has gone back to sheep grazing.

Recently in the extreme northern part of the region in Queensland a very large and well organised attempt has been made to grow grain sorghum on the heavy black soils for pig raising and cattle fattening. So far, yields have been so low, because of unfavourable moisture conditions and insect attack, that the venture has failed to achieve its stated objects. It has had to be greatly curtailed and its future is in doubt.

F. MONSOON REGION

The monsoon region embraces the coastal and in part the sub-coastal lands of northern Australia. It extends from the Kimberley area in the extreme north of Western Australia through the upper portion of the Northern Territory to Cape York Peninsula in Queensland.

The average rainfall of the region varies from 25 to 60 inches per annum and decreases steadily inland. It is monsoonal in character and limited to the summer months, December to March. The monsoon is unreliable and the rainfall is therefore very variable. Summer droughts are relatively common and, as happened recently, sometimes occur in two successive seasons. The other months of the year are almost rainless and temperature remains relatively high, with the result that quite regularly drought persists for about eight months of the year.

The soils consist of lateritic red earths on extensive remnants of old land surfaces, podzolic soils, and smaller areas of alluvial and grey and brown soils of heavy texture. Adjacent to the coast there are large areas of marshy and mangrove country periodically inundated by the sea. Skeletal soils and exposed bare rock are common, particularly in the Kimberley area and in Arnhem Land in the Northern Territory.

The sole major primary industry of the region is

beef cattle grazing. The pasturage is almost entirely of the tall grasses of a tropical savannah woodland, with some open plains. The grass grows rapidly during the monsoon and then dries off to remain as dry feed until the following wet season. Cattle fatten readily while the grass is green, but steadily lose condition in the ensuing dry season, because of the declining quality of the pasture.

As in the adjoining sub-monsoon region (G), stock move from the area generally after they are at least three years old. Some in north-west Australia go direct to the meat works at Wyndham, some are shipped out, some travel by road transport to railheads, but most are driven for long distances over the stock routes before being disposed of. A small fraction are now slaughtered on the north-western cattle stations and the dressed carcasses are flown direct to the freezing works at Wyndham.

Numerous organised attempts have been made to establish a significant area of ploughed land in the Darwin-Katherine area in the monsoon region, but so far they have always failed. At the present time a well organised attempt is being made at and near Katherine towards the southern edge of the region, where a research station has been established by the Commonwealth Scientific and Industrial Research Organization. Here research into both dryland and irrigation farming is going forward. Sorghums, cotton, tobacco, groundnuts, pastures and other crops have been sown in fertiliser, variety and cultivation trials. Results, although not spectacular, have been sufficiently good to encourage a move to apply the more promising methods to tobacco, sorghum, groundnuts and pasture on a demonstration farm. Experimental work with rice on the flood plains of the Adelaide River nearer Darwin is also in progress. Situated on the Ord River just south of Wyndham, the Kimberley Research Station, a joint organisation of the Department of Agriculture of Western Australia and the Commonwealth Scientific and Industrial Research Organization, is primarily concerned with irrigation research on fine-textured soils. Here rice, sugar cane, pastures, and oilseed crops are under investigation. The work has been greatly hampered by the depredations of huge flocks of native birds, which is perhaps a portent of things to come if small isolated areas of crops are developed throughout the region in places where irrigation and other conditions are favourable. The native bird population of the region is without doubt enormous and could well become extremely destructive of local crops designed to increase food supplies.

Near Darwin a small-scale fruit and vegetable industry has grown up. Principally it supplies the local market, but some vegetables such as beans are flown to southern Australia during the winter

months. The gardens depend on ground water for irrigation. Because of the recent great increase in the mining population of the area the fruit and vegetable industry will undoubtedly expand to meet the increased demand. For many years groundnuts have been grown on the light-textured soils of the levee banks of the Katherine River, but not a great deal has been produced, partly because for markets and organisation this crop is so much better placed in Queensland.

G. SUB-MONSOON REGION

The sub-monsoon region extends in a gradually widening and unbroken belt from the Western Australia coastline and the southern Kimberleys through the north central part of the Northern Territory into north-west and central Queensland. The east central portion astride the border of the Northern Territory and Queensland includes the vast open plains of the Barkly Tableland.

The climate of the region, as the name implies, is dry monsoonal. Light rainfall, averaging from 15 to 30 inches per annum and falling almost all in the summer months, and high temperatures characterise the region. The remainder of the year is almost rainless. The rainfall is less reliable than in the monsoon region and may fail almost completely for two seasons in succession.

Here grey and brown soils of heavy texture and brown soils of light texture are predominant; relic lateritic formations and skeletal soils in some areas greatly reduce the value of the country. The heavy-textured soils are the most fertile and usually form open grassy plains; they characterise the Barkly Tableland and the central Queensland area.

As in the monsoon region, beef cattle grazing is the dominant form of land-use, but sheep are grazed at both extremes of the region. They occur in small numbers near the Western Australian coast but in quite large numbers in central Queensland, where they are co-dominant with beef cattle. For the greater part Mitchell and Flinders grasses (*Astrelba* spp. and *Iseilema* spp.), which are of medium height, constitute the bulk of fodder for stock, but shrubs and spinifex play an important part in the areas where sheep are run and on the less fertile soils.

The monsoon and the sub-monsoon region have in common a number of problems connected with the efficient management of the cattle industry. The most pressing of them are inadequate facilities for stock transport and infrequency of water supplies; both appear at the moment to be more important than other problems such as improvement of pastures and breeds of stock. When cattle leave these regions a big percentage of them are driven on the stock routes, frequently for hundreds of miles. They cover about 12 miles a

day and at the end of a long trek they may have lost over 100 pounds weight and deteriorated in quality. The recent use of motor transport on the paved highways between Darwin and Alice Springs and Tennant Creek and Mount Isa to move stock to railheads has done something to improve the situation. It is invariably claimed by the industry that regional beef production could be doubled if the transport problem were solved and more frequent stock-watering facilities provided. With that statement competent observers agree.

Because of the limited distance from water over which stock can graze in long dry periods, the adequate and uniform use of the pasture of the northern areas depends on a sufficiency of water points. In these regions, but particularly in the sub-monsoon region, watering facilities, largely dependent as they are on artesian bores, are not sufficiently numerous to allow uniform pasture utilisation. As a result, in the dry months considerable areas are not grazed at all and pastures near water are overgrazed. The progressive sinking of more bores on stations and stock routes will undoubtedly overcome the problem gradually.

The basic breeds of beef cattle used throughout Australia are British. How far they are truly adaptable to tropical Australia is debatable, but the industry there has been built on them. Some adaptation and selection have been inevitable, and the evidence and opinion of some authorities point to the possibility of complete adaptation in the course of time. Another point of view recognises the need for blood from tropical breeds of cattle and to this end research with Zebu crosses is being pursued by the Commonwealth Scientific and Industrial Research Organization.

In contrast to the sheep-grazed areas of southern Australia a pleasing feature of the monsoon and sub-monsoon regions is their almost complete freedom from signs of man-made erosion. Apart from a few restricted localities such as the Ord River Valley in Western Australia, little serious erosion is evident in northern Australia. Unquestionably this is to a large degree due to grazing by cattle, which are much less destructive than sheep of plant cover because of their top grazing habits.

H. DESERT REGION

The desert region, the largest region of Australia, occupies about two-fifths of the continent and stretches on a wide front from the central areas to the Great Australian Bight in the south and to the coast of Western Australia in the west.

The climate is hot and dry. The annual rainfall averages about 9 inches on the southern edge and 15 inches on the northern margin where it merges into the sub-monsoon region, and falls to about

5 inches in the central areas. It is both unreliable and irregular, and occurs in part in scattered thunderstorms. Consequently there is great variation in precipitation from year to year at any one place. Variation occurs also because the desert, particularly across the centre, is subject to both the southern ocean and the monsoon weather system. In any one year a given locality may get rain from both sources, from only one, or from neither. Hence some years may be almost rainless, which must be kept in mind when stock numbers and their grazing are planned.

The soils of the region are desert loams, relic stony tableland soils, desert sand ridges, shallow red and brown calcareous soils, desert sandplain soils, and some deep red soils of little profile development, as yet unstudied and unnamed. Skeletal soils and bare rock are common in the ranges which traverse the region. Where streams enter the area from adjacent regions their flood plains are characterised by grey and brown soils of heavy texture. The largest significant area where these atypical hydrological and soil conditions prevail is in the north-eastern part of the Lake Eyre basin, and here the so-called channel country makes up a distinctive sub-region shown as H_1 on the map. About one-fifth of the channel country is covered by low-lying, heavy-textured soils which are inundated periodically when normally dry watercourses such as the Diamantina and Cooper's Creek carry flood waters from northern and eastern Queensland. The channel country is potentially the most productive part of the desert region, for each flood is followed by the growth of abundant ephemeral herbage on which stock quickly fatten. Its full utilisation is hampered by the variability in the degree and time of flooding and by lack of transport for the rapid movement of cattle to and from the area as circumstances dictate. Rapid movement of store stock into the area and of fat cattle out of it towards Brisbane or Adelaide is essential to full use of the grazing.

In contrast to the channel country there are two sub-regions, shown as H_2 on the map, which are almost absolute desert of no productivity whatever. The eastern and smaller of the two areas is the Simpson or Arunta Desert, a sea of parallel sand ridges, uninhabited by white man or aboriginal. The second area to the west is a vast tract of sand ridges, stony tablelands and desert mountain ranges embracing the Great Sandy, Gibson and Victoria Deserts; in it there is only a scanty aboriginal population.

For the rest, the desert region provides sparse grazing for sheep and beef cattle; sheep in the west, south and east, cattle throughout, but more particularly to the north and in the central corridor between the two areas of absolute desert. The stock numbers in this large region represent but a

minute fraction of the animal population of Australia and there is little or no apparent prospect of any substantial increase in the numbers. In fact, for the sake of soil conservation, there may be a decrease. Most of the sheep are grazed on perennial shrubs and ephemeral herbage and grasses which appear after rain. The cattle are similarly pastured, but in the north some types of spinifex grass are grazed in addition to the shrubs and ephemerals.

In the northern part of the region the landscape is well preserved; in the south there is notable erosion in some districts, and the perennial bush has been greatly thinned out or killed by too intensive sheep grazing and by the rabbit.

As in the more northerly regions, transport and water supplies are critical problems in some parts of the area. Research into the management of grazing sheep by the Waite Agricultural Research Institute on shrub steppe at Yudnapinna in the region tentatively suggests that an increase in the number of watering points may greatly increase the carrying capacity of the country without detrimental effect, and with a great change in the botanical composition of the pasture. Research on an extended basis to test this finding is now being planned.

There is a great contrast in productivity between the stony tableland soils and the desert loams, the former being very poor. Since the tablelands consistently lie at higher altitudes than the desert loams there may be scope for experiments in diversion of water from them by increasing run-off and then ponding or channelling the additional water on the desert loams where, with more water, experiments in the use of fertilisers with introduced plants such as lucerne might be justified. In this region there is unquestionably an opportunity for bold experimentation with the available water, aimed partly at developing local "fortuitous" irrigation schemes with a minimum expenditure of money and effort on engineering structures.

GENERAL REMARKS

From the regional analysis that has been made it is quite apparent that Australia is essentially a pastoral country through the predominance of animal husbandry and, even more, through the proportion of the continent devoted to grazing. Present development trends are likely to maintain or even increase the devotion to animal industries. From the scientist's point of view the most interesting and certainly attainable improvement to make expansion possible is the increase in artificially fertilised, sown pastures. At present Australia has about 20 million acres of sown pastures, concentrated chiefly in the temperate regions in the south-east and south-west of the continent. Provided certain problems in plant selection and

adaptation can be overcome, establishment of sown pastures may reasonably be expected to spread on a large scale to the sub-humid, tropical and sub-tropical, and monsoon regions. It is estimated that in these and in the temperate regions there are about 100 million acres of land suited in their soil and topography to carrying sown pastures. An example of recent progress (Commonwealth Scientific and Industrial Research Organization, 1953) is the demonstration that *Stylosanthes* may be a suitable pasture plant for the greater part of the monsoon region and for the drier portions of the tropical and sub-tropical regions, where it may ultimately play a part corresponding to that of subterranean clover in the temperate regions.

Arable agriculture in southern and eastern Australia has undoubtedly passed through an era of exploitation, and is now rapidly entering a phase of consolidation and conservation involving some retreat from drier areas and the institution of soil conservation programmes in each of the States and Territories. In northern Australia cultivation of the soil has been spasmodic, fragmentary and of small extent. Currently it is the subject of some research, but its future is as yet uncertain.

At present the greatest activity in land development centres round the settlement of exservicemen from the second world war on farms being made on under- or undeveloped land. On both irrigated and non-irrigated land aggregating some 8.5 million acres, about 6000 new holdings have been created, which have been brought to a preliminary stage of production before occupation. These farms cover all types of production common in Australia but are mostly concentrated in areas of sheep-raising, dairying and mixed farming, with fruit-growing on irrigated land. There is also considerably activity on the part of private enterprise by both individuals and companies. In Australia a widely known instance of private enterprise is the development and subdivision of a vast tract of land by the Australian Mutual Provident Society in the sub-humid region in South Australia, and the settlement on it of individual farmers for sheep raising, a project depending almost entirely on the results of recent research on pasture establishment by Riceman (1948). To date, 60,000 acres have been sown to pasture and another 100,000 acres are in course of preparation. Individual development projects take the form of in-

creased or renewed activity by landholders whose income from primary products, especially wool, have recently been much increased. There has been a wave of prosperity also in the cities. An appreciable proportion of larger city incomes is being devoted, as an investment, to the purchase and improvement of large tracts of land.

The limit to irrigation development in Australia is set not by acres of suitable land but by the amount of available water, which is demonstrably small for a continental mass: for instance, the flow of Australian rivers is but one-twentieth of that of the United States with much the same land area. Because of the general dryness of the climate and the extraordinarily small flow of the streams, there appears to be a total of only about 20 million acre-feet of water available for irrigation after urban and other requirements are met. Half, or nearly half, the amount is already in use, and much of the remainder is committed to projects in some stage of planning or construction.

Pest control in Australia and its effect on the production and preservation of foodstuffs and other primary products has received great assistance from the recent development of insecticides, weedkillers and fungicides. Means for the ultimate control of the plague locust, for example, are now almost in sight. The recent spectacular success with myxomatosis in controlling the rabbit has led to a rapid increase in production, detectable not only in the statistics of the primary industries but also by any competent observer travelling in the country.

It is interesting to speculate how the development of primary production in Australia, as far as it can be foreseen, will influence the population of the continent. Estimates made in terms of current achievements in primary and secondary industrial technology might be significantly altered by possible future developments in such fields as atomic energy or artificial rain-making, but according to a recent statement by Bowen (1954) the prospects do not seem very promising. Unquestionably the more arid half of the country can support no more people. The other half can probably ultimately double or treble its production. This increase, coupled with the standard of living envisaged for the future population, will determine the size of the population. We might reasonably foretell a future population, with the present standard of living, of at least from 20 to 25 million.

Carbohydrate Constituents

4035

- TULLER, E. F. and KEIDING, N. R. **Determination of protein-bound carbohydrates by the anthrone reaction. Effect of tryptophan.** *Anal. Chem.*, 1954, **26**, 875-878. [George F. Baker Clin. Res. Lab., New England Deaconess Hosp., Boston, Mass.]

The presence of tryptophan introduces an error of 5 to 15 per cent. in the estimation of carbohydrates in terms of the anthrone reaction, owing to the formation of a complex. This error can be corrected for by means of a nomogram prepared by the application of the anthrone reaction to known mixtures of tryptophan and sugars.—H. G. Bray.

4036

- LEMIEUX, R. U. and BAUER, H. F. **Spray reagent for the detection of carbohydrates.** *Anal. Chem.*, 1954, **26**, 920-921. [Nat. Res. Council, Prairie Reg. Lab., Saskatoon, Sask.]

The reagent consists of an aqueous solution of periodate and permanganate at pH 7.2. Any substance which reduces these compounds gives a greenish-yellow spot on a paper chromatogram, the background being permanganate colour.

H. G. Bray.

HUYGENS, R. and CASIMIR, J. Séparation chromatographique sur papier du saccharose, du glucose, du fructose et du sorbitol. [Chromatographic separation on paper of sucrose, glucose, fructose and sorbitol.] *Bull. Inst. agronom. Gembloux*, 1953, **21**, No. 3/4, 8–13.

Two techniques are described. In the first, two-dimensional chromatograms were prepared by a modification of the method of Jeanes *et al.* (Abst. 1274, Vol. 21). The solvents used were a mixture of benzene, butanol and pyridine and water (1:5:3:3) in one direction and a mixture of either fusel oil, pyridine and water (1:1:2) or of isopropanol, acetic acid and water (7:2:1) in the other. Two chromatograms were prepared. One was developed with sodium taurocholate followed by benzidine (*cf.* Horrocks, Abst. 3022, Vol. 19) and the other with silver nitrate to reveal sorbitol as described by Trevelyan *et al.* (Title 3059, Vol. 20). The second technique was one-dimensional for 150 hr., using the method with a tampon of cotton wool fixed at the bottom of the paper as described by Miettinen and Virtanen (*Acta chem. scand.*, 1949, **3**, 459). The solvent used was fusel oil, pyridine and water (1:1:2) or benzene, butanol, pyridine and water (1:5:3:3).

WYLAM, C. B. Analytical studies on the carbohydrates of grasses and clovers. 4. Further developments in the methods of estimation of mono-, di- and oligo-saccharides and fructosan. *J. Sci. Food Agric.*, 1954, **5**, 167–172. [Dept. Chem., Univ. Edinburgh.]

For previous parts see Absts. 27, Vol. 22; 1677, Vol. 24.

The oligosaccharides present in perennial ryegrass were examined and the presence of raffinose,

Vol. 24, No. 4

melibiose and stachyose was established. A method for their estimation is described with minimum decomposition of fructose. A complete scheme is given for the estimation of a mixture of sugars in fresh and ensiled materials. The stability of different sugars to acid hydrolysis was studied, sugars being estimated by the Somogyi iodimetric method. Fructose was the only sugar to suffer decomposition. In a mixture of sugars subjected to electrodialysis for 30 min., ribose showed a preferential migration of 15 per cent. in relation to sucrose, glucose, fructose and xylose. The organic acids in silage were shown not to cause hydrolysis of sucrose or other labile substances under the conditions of the experiment.

4048

KAHAN, J. Estimation of hexose diphosphate. *Arch. Biochem. Biophys.*, 1954, **48**, 331–337. [Dept. Pharmacol., Karolinska Inst., Fac. Med., Stockholm.]

The method is based on the estimation of the total carbohydrate, rather than the fructose, content of hexose diphosphate, with an anthrone reagent applied directly to a solution of the compound (5 to 400 μ g. per 1.5 ml.); the absorption of the reaction mixture at 625 m μ . is measured. The method is applicable also to a barium-insoluble, alcohol-insoluble fraction [LePage and Umbreit, *J. Biol. Chem.*, 1943, **147**, 263] of powdered tissue, a correction being applied for pentoses present in adenosinetri- and -diphosphates and similar compounds. The experimental error is 2.4 per cent.

4051

MOXON, A. L. and BENTLEY, O. G. Some discrepancies in A.O.A.C. crude fiber and N.F.E. values in roughages. *J. Animal Sci.*, 1953, **12**, 925. *Proc.* [Ohio Agric. Exp. Stat.]

4052

THACKER, E. J. **A modified lignin procedure.** *J. Animal Sci.*, 1954, **13**, 501-503. [U.S. Plant, Soil, Nutrit. Lab., Bur. Plant Indust., Ithaca, N.Y.]

The lignin method of Ellis *et al.* (Abst. 2495, Vol. 16) was modified (1) by the introduction of a treatment with 0.25 per cent. Na_2CO_3 as suggested by Forbes and Hamilton (Abst. 2363, Vol. 23) and (2) by the use of an autoclave for 10 min. at 20 lb. pressure instead of refluxing with acid for 1 hr. The treatment with Na_2CO_3 had the greater effect, reducing the crude lignin yield (by about 20 per cent.), and it is suggested that this probably reflects a reduced N content of the crude lignin. Autoclaving had only a small reducing effect on the lignin yield.—D. M. Walker.

Nitrogenous Constituents

4053

BRANDENBERGER, H. Über die Verwendung von Cellulose als Adsorbens für Blutplasma-Proteine aus wässriger Lösung. [On the use of cellulose as adsorbent for blood plasma proteins from aqueous solution.] *Helv. chim. Acta*, 1954, **37**, 97-103. [Theodor-Kocher-Inst., Univ. Berne.] English summary.

Cellulose powder retains fibrinogen but not the other main proteins of serum. Changes in the properties of globulins during chromatography are discussed.—H. G. Bray.

4054

HARDWICKE, J. **The estimation of serum proteins by electrophoresis on filter paper.** *Biochem. J.*, 1954, **57**, 166-171. [Dept. Exp. Pathol., Univ. Birmingham.]

An account of a procedure which is a modification of that of von Turba and Enekel (*Naturwissenschaften*, 1950, **37**, 93). Factors affecting accuracy were examined; the modification described was accurate to within 6 per cent. of the total amount of protein present.—H. G. Bray.

4055

McKINLEY, W. P., MAW, W. A., OLIVER, W. F. and COMMON, R. H. **The determination of serum protein fractions on filter paper electropherograms by the biuret reaction, and some observations on the serum proteins of the estrogenised immature pullet.** *Canad. J. Biochem. Physiol.*, 1954, **32**, 189-199. [Fac. Agric., McGill Univ., Macdonald Coll., Que.]

The protein is located on a reference electropherogram with naphthalene black and eluted with 1 per cent. saline from the appropriate parts of an unstained strip. A biuret reaction is applied to the eluate and the colour obtained is measured in a colorimeter. A comparison was made

between the mobilities of serum protein fractions from man and the domestic fowl, and observations on the serum proteins of immature pullets treated with oestrogen are reported.—H. G. Bray.

4056

DISCOMBE, G., JONES, R. F. and WINSTANLEY, D. P. (with DALY, C.) **The estimation of γ -globulin.** *J. Clin. Pathol.*, 1954, **7**, 106-109. [Central Middlesex Hosp., London.]

A method of electrophoresis on paper is described; the separated bands are stained with Lissamine green S.F. 130 and an approximate estimation of their protein content is made photometrically. The procedure is particularly useful in the diagnosis of myelomatosis and nephrotic nephritis. It is concluded that the Kunkel ZnSO_4 turbidity test (Abst. 145, Vol. 18), which gives similar results for γ -globulin, is more suitable than electrophoresis for following the progress of a disease.—H. G. Bray.

4059

ADJUTANTIS, G. **Electrophoretic separation on filter paper of the soluble liver-cell proteins of the rat borate buffer.** *Nature*, 1954, **173**, 539-540. [Dept. Chem. Pathol., Postgrad. Med. Sch., Ducane Rd., London, W. 12.]

Concentration of liver proteins without denaturation is achieved by a combination of freeze-drying and homogenisation, soluble proteins being separated by fractional centrifuging. Electrophoresis revealed 5 main protein components.

H. G. Bray.

4060

BAKER, L. C., LAMPITT, L. H. and BROWN, K. P. **Connective tissue of meat. 3. Determination of collagen in tendon tissue by the hydroxyproline method.** *J. Sci. Food Agric.*, 1954, **5**, 226-231. [The Lyons Laboratories, 149 Hammersmith Rd., London, W. 14.]

Samples of collagen were prepared from defatted, freeze-dried tendon dissected from shin of beef by

treating the material in 0.1 *N* NaOH to remove cellular material and adhering muscle protein. It was washed and dissolved in 0.01 *N* HCl and the collagen was reprecipitated by neutralisation. Alternatively the method of Bowes and Kenten (Title 4494, Vol. 18) was used. The samples had a maximum hydroxyproline content of 13.2 per cent., which gave a factor of 7.57 for converting hydroxyproline to collagen. Estimation of hydroxyproline in a direct acid hydrolysate or in an acid hydrolysate of an aqueous autoclave extract gave comparable results. The results obtained by a modification of the method of Lowry *et al.* described by the present authors (Abst. 193, Vol. 23) gave slightly higher results.—W. Godden.

4061

ROSE, D. (TESSIER, H. and MARIER, J.) **Estimation of protein denaturation in frozen milk.** *Canad. J. Technol.*, 1954, **32**, 78-84. [Div. Appl. Biol., Nat. Res. Labs., Ottawa.]

An investigation was made of the conditions under which more exact information on protein denaturation might be obtained than that provided by the measurement of the volume of solids precipitated after standardised centrifuging. From the studies it was concluded that skimmed milk should be used, thawing should be for a fixed time at or below 4°C., temperature during treatment should be kept below 21°C., centrifuging should be for at least 10 min. at over 500 *g* at the tip of the tube and that after being mixed the supernatant milk should be analysed for total N and both loss of N and volume of precipitate should be recorded.—D. Harvey.

4062

SALWIN, H. **Biuret method for soluble whey proteins in nonfat dry milk solids.** *Food Res.*, 1954, **19**, 235-245. [Quartermaster Food and Container Inst. Armed Forces, Chicago, Ill.]

Protein in whey is precipitated with trichloroacetic acid, separated by centrifuging and dissolved in 3 per cent. NaOH and the intensity of the biuret colour produced on the addition of 5 per cent. CuSO₄ is measured at 560 mμ.

H. G. Bray.

BABIN, V. A. and MUSERSKII, I. I. **Uskorennoe opredelenie belkov v golobykh blyudakh i ratzionakh. [The rapid estimation of proteins in prepared dishes and rations.]** *Vop. Pitan.*, 1954, **13**, No. 3, 34-40. [Nauch.-Issled. Sanit. Inst., Mosk. Oblast.]

The method of Djermillo gave results which, compared with results obtained by Kjeldahl analysis showed the method to be rapid and accurate. The method, which depends on fusing

with sodium hydroxide and fused sodium acetate, is described in detail, as is the construction of the apparatus.—D. W. Taylor.

4064

MILLER, S., RUTTINGER, V. E., KOVACH, E. S. and MACY, I. G. **The amino acids in nine food proteins as determined by three methods.** *Pan Amer. Med. Women's J.*, 1952, **59**, 9-13; 17; 24. [Res. Lab., Child. Fund Michigan, Detroit.]

Amino-acids were estimated in 6 food proteins, some of animal and others of vegetable origin. Of the 11 acids estimated, both microbiological and chromatographic methods were used for 5, microbiological alone for 4, chromatographic alone for 1 and microbiological and chemical for 1. Of 11 other co-operating laboratories 2 used only chemical and 9 only microbiological methods. The average and range values for these laboratories are given. Samples of edestin, gelatine, and casein and 2 of dried whole human milk were also analysed for 6 amino-acids. Certain more or less consistent differences between the results by microbiological and chromatographic methods were recorded for all foods, but the direction of difference varied with the amino-acid. It is concluded that both methods have inherent errors and that the value for an amino-acid in a protein can be considered as correct only if it is the same by both methods. Results for histidine in edestin and casein obtained by the chemical method were only about half those obtained by a microbiological method, though results for gelatine showed reasonably good agreement by both methods.—W. Godden.

4065

HESS, E. L. and YASNOFF, D. S. **A method for determining the solubility characteristics of components in protein mixtures.** *J. Amer. Chem. Soc.*, 1954, **76**, 931-933. [Rheumatic Fever Res. Inst., Northwestern Univ. Med. Sch., Chicago, Ill.]

The 2 systems 2-butanol:3 per cent. NH₄OH (3:1) and 72 per cent. phenol resolve 16 amino-acids adequately for direct photometric measurement of the intensity of ninhydrin spots. Other

systems suitable for tryptophan and histidine are described.—H. G. Bray.

4068

MONTREUIL, M. and KHOUVINE, Y. Dosage des acides aminés par les complexes colorés dicétohydrin-dylidène - hydrindamine - sels de cadmium. [Estimation of amino-acids by the coloured complexes diketohydrindylidene-hydrindamine salts of cadmium.] *Bull. Soc. Chim. biol.*, 1954, **36**, 425-428. [Inst. Biol. Phys. Chim., Paris.]

The position of amino-acids separated by paper chromatography is revealed by dipping the sheet in an ethanolic solution of ninhydrin. The relevant portions are cut out and treated in a test tube with an aqueous methanolic solution of CdCl_2 . A red complex which is formed is eluted from the paper with methanol and estimated colorimetrically. The method is applicable to all common amino-acids except proline, hydroxyproline, cysteine, cystine and methionine.

ROINE, P., GYLLENBERG, H. and SALAKIVI, V. Determination of "Streptogenin" with *Lactobacillus bifidus*. *Acta chem. scand.*, 1954, **8**, 161-165. [Dept. Nutrit. Chem., Univ. Helsinki.]

It has previously been shown that streptogenin is essential for the growth of *Lactobacillus bifidus* (Gyllenberg *et al.*, *Acta chem. scand.*, 1953, **7**, 694). Three strains were isolated from the faeces of breast-fed infants incubated in the medium of Hassinen *et al.* (Abst. 368, Vol. 22). Tests with these in which the anaerobic conditions required by *L. bifidus* were established by using a large inoculum showed that, as a test organism, it has the following advantages: the blank values are always very small, the growth response is pronounced and the basal medium is simple. Figures

obtained for the streptogenin activity of 13 different preparations are in good agreement with those obtained by the *L. casei* method of Kodicek and Mistry (Abst. 1594, Vol. 22).—W. Godden.

THUILLIER, Y., FAUCONNEAU, G., DE PRAILAUNE, S., CHEVILLARD, L. and ROCHE, J. Dosage de la méthionine dans les produits végétaux employés dans l'alimentation animale. [Estimation of methionine in plant products used in animal nutrition.] *Ann. Zootec.*, 1954, **3**, 29-45. [Lab. Biochim. Gen. Comparée, Coll. France.]

Methionine in vegetable feedingstuffs was estimated microbiologically, with *Lactobacillus arabinosus* 17/5, *Leuconostoc mesenteroides* P-60 or *Lactobacillus fermenti* 36. From these studies *L. mesenteroides* proved the most specific, but it could not be used for fodders poor in N. *L. arabinosus* was most generally useful and details are given of conditions of hydrolysis. *L. fermenti* was less sensitive. Results for yeasts, oilcakes, grains, and fresh and dry fodders agreed with those of Singleton *et al.* (Abst. 1465, Vol. 23) and Armstrong (Abst. 1548, Vol. 21).—M. B. Richards.

4073

SCHORMÜLLER, J. and LEICHTER, L. Die Wirkung verschiedener Hydrolysebedingungen auf die Freisetzung von Lysin aus Casein. [Effect of different conditions of hydrolysis on the liberation of lysine from casein.] *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1953, **97**, 446-456. [Inst. Lebensmittelchem., Tech. Univ., Berlin-Charlottenburg.]

Investigations were made on the enzymic and chemical liberation of lysine from casein under different conditions of hydrolysis. Treatment with tryptic enzymes and papain gave the highest yields of free lysine, treatment with pepsin the lowest. Acid hydrolysis with HCl, HBr, HI, formic acid, or a mixture of formic acid and HCl, showed that the usual procedure under normal pressure liberated the whole of the lysine present in the casein. Conditions were established for the optimum liberation of lysine under hydrolysis with HCl or HBr in the autoclave, and the extent of lysine destruction and racemisation was estimated. Alkaline hydrolysis with NaOH led to considerable destruction of lysine. By combining an enzymic and a chemical method of lysine estimation, a reliable estimate could be obtained of the yield of natural L-lysine, and of the amounts racemised and destroyed.—M. B. Richards.

4074

SCHRAM, E., MOORE, S. and BIGWOOD, E. J. Chromatographic determination of cystine as

N.A. and R., October 1954

cysteic acid. *Biochem. J.*, 1954, **57**, 33-37.

[Lab. Biochem., Fac. Med., Univ. Brussels.]

The protein is oxidised with performic acid and hydrolysed and the cysteic acid formed is separated on a column of a basic ion exchange resin (Dowex) and eluted with chloroacetic acid. The cysteic acid in the appropriate fractions is estimated by a ninhydrin method.—H. G. Bray.

4075

STRICKLAND, R. D., MARTIN, E. L. and RIEBSOMER, J. L. **A method for the independent determination of cysteine and cystine in proteins.** *J. Biol. Chem.*, 1954, **207**, 903-910. [Dept. Chem., Univ. New Mexico, Albuquerque.]

The method is based on the condensation of the cysteine sulphhydryl groups in the intact protein with formaldehyde, with which cystine does not react. The mixture is then hydrolysed with 6 N HCl and cystine is precipitated as cuprous mercaptide. This is filtered off and converted in a Parr bomb to sulphate and weighed as such. Methionine, after demethylation, is removed by precipitation with cuprous copper. The filtrate, which contains the cysteine as thiazolidinecarboxylic acid, is evaporated to dryness and the residue is ashed in a Parr bomb, the S being weighed as BaSO₄. Recovery experiments under a variety of conditions gave figures of 95 to 103 per cent. for samples containing about 20 mg. cystine plus cysteine.—C. Warner.

LYONS, J. and O'SHEA, M. J. **Factors affecting the Gerber weighing method of testing cream.** *J. Dept. Agric., Republic of Ireland*, 1952-53, **49**, 56-81. [Dept. Dairy Technol., University Coll., Cork.]

This is a critical examination of the estimation of fat in cream by the Gerber method under conditions laid down by the Department of Agriculture, Ireland, 1937, Bull. No. 4, and by the British Standards Institution (Abst. 2910, Vol. 6), respectively. It is shown that in both cases there are numerous sources of error, which under practical conditions with the Irish method may lead to limits of variation of ± 1.26 per cent. in the fat reading from the true average fat reading and with the British Standard method of ± 1.66 per cent. With the Irish method, under commercial conditions, 75.4 per cent. of the tests should not differ by more than 0.5 per cent. and 99.7 per cent. by not more than 1.0 per cent. from the true average reading. With the British method the figures would be 47.2 per cent. and 98.3 per cent. for the same limits.—W. Godden.

GERTLER, M. M., KREAM, J. and BATURAY, O. Studies on the phosphatide content of human serum. *J. Biol. Chem.*, 1954, **207**, 165-173. [Dept. Biochem., Home for Aged and Infirm Hebrews, New York.]

A micro-method is described for the analysis of plasma phospholipins. A mixture of ethanols and ether is used to extract the phospholipins, which are then hydrolysed for 48 hr. to yield free serine,

N.A. and R., October 1954

ethanolamine and choline. The bases are separated on paper chromatograms with a mixture of *n*-butanol, diethylene glycol and water, 4:1:1 by volume, as solvent. Serine and ethanolamine are quantitatively estimated by development of the adsorbed zones with ninhydrin, followed by extraction of the coloured areas with aqueous pyridine and measurement of the intensity of absorption at 580 $m\mu$. in a Beckman spectrophotometer. Choline is estimated on separate chromatograms according to the method of Levine and Chargaff (Abst. 4478, Vol. 21).

A few representative analysis of human serum phospholipins are given, showing that choline-containing phospholipins are the major constituent. G. A. Garton.

MARKEES, S. **Chromatography of pyruvic acid and of acetoacetic acid as their 2:4-dinitrophenylhydrazones.** *Biochem. J.*, 1954, **56**, 703-704. [Med. Labs., F. Hoffmann-La Roche and Co., Ltd., Basle.]

Paper chromatography of the 2:4-dinitrophenylhydrazone of pyruvic acid using a butanol: ammonia: water mixture as developing solvent gives 2 spots, one of which has an R_f value somewhat similar to that of the 2:4-dinitrophenylhydrazone of acetoacetic acid. The normal product obtained by reaction of blood acetoacetic acid with 2:4-dinitrophenylhydrazine is, however, the hydrazone of acetone, which gives a spot quite distinct from either of the pyruvic acid spots. Acetoacetic acid 2:4-dinitrophenylhydrazone is formed only when the concentration of blood acetoacetic acid is high.—H. G. Bray.

VANATTA, J. C. and CUSHING, I. **The determination of total base serum with an ion exchange resin conditioned as iodate.** *J. Biol. Chem.*, 1954, **208**, 195-204. [Dept. Physiol., Southwestern Med. Sch., Univ. Texas, Dallas.]

The use of a Rohm and Haas IRA-400, analytical grade resin in the hydroxyl form is recommended. It is conditioned by running slowly through 200 ml. of the resin in a column 30 to 40 mm. in diameter, 9200 ml. of 5 per cent. KIO_3 . Such a resin has the advantage over that recommended by Polis and Reinhold (Abst. 2921, Vol. 14) that it will react stoichiometrically with both carbonate and bicarbonate and the iodate liberated can be estimated accurately by standard analytical methods. It can be used for fresh or ashed serum, but in

unashed sera the results are on the average 4.8 m. equiv. per litre lower than those for the same sera estimated by the ashing method. The method on fresh and ashed serum was compared for 11 normal samples and 8 from hospital patients with the ashing method of Hald (Abst. 3857, Vol. 3) and good agreement was found between the results by the ashing methods.—W. Godden.

4111

SHENK, W. D. **Tissue chloride.** *Arch. Biochem. Biophys.*, 1954, **49**, 138–148. [Zool. Lab., Univ. Pennsylvania, Philadelphia.]

Because of doubts about the accuracy of the Van Slyke method for chloride when applied to tissue, chloride was estimated by the Volhard method or gravimetrically in wet and dry frog muscle after ashing in the Parr bomb or the micro-Carius furnace. There was good agreement between the 2 methods of ashing, but the results were at least 100 per cent. higher than those by the Van Slyke method. For blood of 5 species. however, the values obtained by the micro-Carius method were in agreement with values in the literature obtained by the Van Slyke method. It is suggested that tissue chloride not detected by the Van Slyke method may be present as chloranil.

Values for the chloride content of a number of wet tissues of dog and rabbit are given.

4129

MITCHELL, T. A. **The spectrophotometric determination of magnesium with thiazol yellow dyes.** *Analyst*, 1954, **79**, 280-285. [Dept. Agric., Rukuhia Soil Res. Stat., Hamilton, N.Z.]

The thiazole yellow method is critically discussed. A procedure is described whereby Mg is precipitated as its ammonium phosphate, redissolved, and estimated in this solution. Starch is used as a protective colloid and glycerol to stabilise the colour. In 14 control experiments the recovery of Mg, 30 to 60 $\mu\text{g.}$ added to plant extracts, ranged from 93 to 107 per cent. The standard deviations of 10 estimations made on 10 dilutions of a standard solution with 116 $\mu\text{g.}$ per ml. ranged from 1.2 to 6.9.

Miscellaneous

4142

VENKATESWARLU, P. and NARAYANA RAO, D. **Investigations on the removal of fluoride from water: rapid removal of fluoride with magnesium oxide.** *Indian J. Med. Res.*, 1953, **41**, 473-477. [Dept. Biochem., Med. Coll., Trivandrum.]

Data are given on the treatment by boiling for 5 min. with light or heavy MgO of water samples containing 5, 10 or 20 p.p.m. F. Removal was most effective with light MgO and was greater than reported by Elvove (Abst. 2889, Vol. 7). The oxide could be re-activated by ignition and used on a number of occasions.—D. Harvey.

4143

VENKATESWARLU, P. and NARAYANA RAO, D. **Investigations on the removal of fluoride from water: factors governing the adsorptions of fluoride by magnesium oxide.** *Indian J. Med. Res.*, 1954, **42**, 135-140. [Dept. Biochem., Med. Coll., Trivandrum.]

In laboratory investigations further to those described in the preceding abstract the possibility was studied of eliminating the need for boiling and so making the method applicable to public water supplies. The effects of temperature and time of treatment and of concentrations of F and MgO were examined and the findings are reported in a series of graphs.

Warming the water to 40° C. with stirring after the addition of an amount of MgO calculated for the F content of the water and subsequent filtration are recommended.—D. Harvey.

BENNETT, A. and HUDSON, J. R. **Study of methods for determination of moisture in malt.** *J. Inst. Brewing*, 1954, **60**, 35-42. [Brewing Indust. Res. Found., Nutfield, Surrey.]

The Institute of Brewing standard water-oven method of estimating moisture in malt (*J. Inst. Brewing*, 1948, **54**, 179) was compared with 3 other methods, drying *in vacuo* at a series of temperatures between 40° and 100° C., titration with Karl Fischer reagent, and distillation with a water-immiscible liquid in a Dean and Stark apparatus. For grinding the malt a special steel mortar was devised. The 4 methods are described in full and results obtained with them are tabulated for 7 samples. Those by the Institute's standard method were always substantially lower than those for the other 3, which were in fair agreement. The causes of the discrepancy were investigated

by the principle of differential thermal analysis, and it was concluded that in the process of oven drying enzymic hydrolysis of the starch or protein constituents of the malt led to some of the water becoming chemically bound. For practical routine purposes the Karl Fischer titration is recommended as quickest and easiest.—E. M. Hume.

SCIENTIFIC COMMITTEE FOR THE STANDARDIZATION OF METHODS FOR THE ANALYSIS OF MILK AND DAIRY PRODUCTS. **Standardization of methods for the analysis of milk and dairy products in the Netherlands. 6. The determination of the titratable acidity of milk.** *Nederlands Melk Zuiveltijdschr.*, 1953, **7**, 246-250. [Govt. Dairy Stat., Leyden.]

Full details are given of the standardised apparatus, solutions and methods to be used in the Netherlands in estimating the titratable acidity of milk, so that results obtained in different laboratories may be comparable. The Standard Specification is designed for the analysis of whole milk, "standardised liquid milk", partly or completely skimmed milk, buttermilk, acidified partly or completely skimmed milk, and whey. For titration of 10 ml. of the undiluted sample 0.50 ml. of 2 per cent. phenolphthalein in ethanol is used as indicator. The end-point is determined by comparing the colour with a "standard colour" obtained by adding 0.50 ml. of a 0.0005 per cent. solution of "Basic Fuchsin" to 10 ml. of the sample. Titration is with 0.1 N NaOH. As the sample is not diluted, the method cannot be used for very viscous products such as cream or condensed milk; for these a special method will be designed.—M. B. Richards.

4149

SCIENTIFIC COMMITTEE FOR THE STANDARDIZATION OF METHODS FOR THE ANALYSIS OF MILK AND DAIRY PRODUCTS. **Standardization of methods for the analysis of milk and dairy products in the Netherlands. 7. The determination of the density of buttermilk, acidified skimmed milk, and "yogurt milk" at 20° C with a lactodensimeter.** *Nederlands Melk Zuiveltijdschr.*, 1954, 8, 34-36. [Govt. Dairy Stat., Leyden.]

The conditions to be observed in the use of the densimeters previously described (Abst. 3931, Vol. 23) and the pre-treatment which is necessary when estimating the density of the above milk products are outlined in detail.—W. Godden.

KIELANOWSKI, J. and OSIŃSKA, Z. **Metody określenia zawartości tłuszczu i mięsa w tuszach tuczników mięsnych. [Methods for estimating fat and lean content of bacon carcasses.]** *Rocz. Nauk rol.*, 1954, 67, 173-191. [Inst. Zootech.] English and Russian summaries.

The investigation was designed to establish indices for the estimation of lean and fat content of bacon carcasses without detailed dissection. Such indices would be of value to progeny testing stations.

The right sides of 32 carcasses were measured and cut up according to a routine procedure and the prime cuts were dissected into fat, lean, bone and skin. Simple and multiple correlations were computed between different measurements and weights on the one hand and the total yield of meat and fat of the prime cuts on the other.

A highly significant correlation ($r = +0.606$) was found between the lean content of the prime cuts and the width of the eye of loin, but the correlation between lean content and the depth of eye was low and not significant ($r = +0.203$).

Fat thickness measured at the cranial margin of the section of the gluteus muscle showed the highest and highly significant correlation ($r = +0.841$) with the fat content of the prime cuts; lower, but still significant, correlations were shown by the other rump measurements ($r = +0.766$ and $+0.767$) as well as by the shoulder measurement ($r = +0.723$) and the loin fat measurement ($r = +0.627$). (From English summary.)—W. Godden.

4151

PRICE, S. A. and BOUCHER, K. A. **The assay of penicillin in compound feeding stuffs.** *Analyst*, 1954, 79, 150-158. [Walton Oaks Exp. Stat., Vitamins, Ltd., Dorking Rd., Tadworth, Surrey.]

Vol. 24, No. 4

A large-plate method with *Bacillus subtilis* as test organism is described. Samples of feeding-stuff are extracted with methanol and the extracts are taken up on paper discs which are applied to the medium.—H. G. Bray.

4152

ANDERSON, D. G. and VENNESLAND, B. **The occurrence of di- and triphosphopyridine nucleotides in green leaves.** *J. Biol. Chem.*, 1954, 207, 613-620. [Dept. Biochem., Univ. Chicago, Ill.]

The method employed for preparation of concentrated extracts of the nucleotides was a combination and modification of the methods of Fiegelson *et al.* (Title 3126, Vol. 20) and of LePage (*J. Biol. Chem.*, 1947, 168, 623; 1949, 180, 975). The final estimation of diphosphopyridine nucleotide was by measurement of the increase in light absorption at 340 m μ . in the presence of alcohol and yeast alcohol dehydrogenase, and of triphosphopyridine nucleotide similarly in the presence of glucose-6-phosphate and glucose-6-phosphate dehydrogenase. Both nucleotides were found in the green leaves of bean, maize, tomato, parsley, pea and spinach plants in approximately equal amounts varying from 2.6 to 13.7 μ g. per g. fresh material according to the species.—W. Godden.

4153

GRUSZCZYŃSKI, T. and KMIECIK, J. **Badanie krajowych konserw z owoców pestkowych na zawartość cyjanowodoru. [Estimation of the hydrocyanic acid content of locally produced canned kernel fruits.]** *Rocz. Państwowego Zakł. Hig.*, 1954, 5, 109-114. [Stac. San.-Epid., Kielcach.] Russian and English summaries.

Hydrocyanic acid was estimated in stewed stone fruits locally grown. Only traces of free HCN were occasionally found. The quantity of total HCN, free and combined, found never exceeded 0.5 mg. per 100 g. stewed fruit. (From summary.) W. Godden.

4154

FEULGEN, R., BOGUTH, W., SEYDL, G. and ANDRESEN, G. **Der "Plasmalogentest" und der "Farbquotient der Acetalphosphatide" im Blutserum. [The "plasmalogen" test and the "colour quotient of acetal phosphatides" in blood serum.]** *Hoppe-Seyler's Ztschr.*, 1953, 295, 271-277. [Physiol. Chem. Inst., Justus-Liebig-Hochsch., Giessen.]

A simpler method of estimating plasmalogen (see Abst. 3065, Vol. 21), for use on a macro- or micro-scale, is described; it takes about 1 hr. and is claimed to be accurate to ± 2.5 per cent.

Values are given for man and domestic animals. They appear to be characteristic of the species; in cattle they rise with age.—W. M. Deans.

4155

THALER, H. and SOMMER, G. Studien zur Farbstoffanalytik. 5. Nachweis und Identifizierung wasserlöslicher Teerfarbstoffe in Lebensmitteln. [Studies in pigment analysis. 5. Demonstration and identification of water-soluble aniline dyes in foods.] *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1953, **97**, 441-446. [Deutsch. Forschungsanst. Lebensmittelchem., Munich.]

In the demonstration and identification of water-soluble aniline dyes in foods by paper chromatography, considerable interference is caused by proteins, carbohydrates, minerals and other substances which go into solution along with the dyes. A highly specific method of isolating the aniline dyes consists in absorbing them on wool, from which they are readily extracted again in a state of purity by dilute ammonia, this ammoniacal solution being then used for the chromatographic identification. Instructions are given for the application of the method to a series of foodstuffs of different kinds, those with a starch or gelatine basis, and those containing much sugar or fat.

upsalien., 1954, **59**, 241-242. [Pharmacol. Inst., Univ. Upsala.]

Several test substances, preferably isotopic, are injected at different times, with suitable intervals, into a body fluid. Their concentrations are estimated in one and the same sample of the fluid drawn after a suitable lapse of time. This gives several points on a time-concentration curve from the analysis of only one sample, and can be used to measure, *e.g.*, rate of flow of a body fluid, such as aqueous humour, when a succession of samples cannot be taken.—W. Godden.

4174

HORN, M. J., BLUM, A. E. and WOMACK, M. **Availability of amino acids to microorganisms. 2. A rapid microbial method of determining protein value.** *J. Nutrition*, 1954, **52**, 375-381. [Bur. Human Nutrit., Agric. Res. Admin., U.S. Dept. Agric., Washington, D.C.]

To a basal medium containing no amino-acid 3 preparations of cottonseed meal were added at 5 levels of protein and the resulting growth of a strain of *Leuconostoc mesenteroides* was measured. The preparations were an enzymic digest of the processed meal at pH 6.8, an enzymic digest of unprocessed meal at pH 6.8 and an acid digest of unprocessed meal filtered at pH 4.0, supplemented with tryptophan in the amount found in cottonseed meal and adjusted to pH 6.8. The ratio of the protein efficiency of a processed to that of an unprocessed meal was expressed as a percentage. Two series of cottonseed meals were thus investigated and the protein efficiency percentage values were compared with those obtained in rat-feeding experiments. With one exception the indices of protein efficiency obtained by the methods followed the same order. The method can be extended to other types of foodstuff.—M. J. Dobson.

4175

FEINSTEIN, A. R., BETHARD, W. F. and MCCARTHY, J. D. **A new method, using radioiron, for determining the iron-binding capacity of human serum.** *J. Lab. Clin. Med.*, 1953, **42**, 907-914. [Dept. Med., Univ. Chicago, Ill.]

Radio-active Fe, in reduced form, of known specific activity is added to serum in amount greater than that required to saturate the protein. The mixture is allowed to stand 15 min. at room temperature; the Fe-saturated protein is precipitated with neutral saturated ammonium sulphate and separated by filtration and centrifuging. The excess of unbound radio-active Fe is measured; from this value and the original activity of the solution the amount of Fe bound is calculated. The method gives results in agreement with those obtained by spectrophotometric methods but has

the advantage of greater accuracy. It is applicable to a wider range of types of sera, *e.g.*, jaundiced serum and serum which is older than 24 hr.

W. Godden.

4176

McDOWELL, R. E., LEE, D. H. K. and FOHRMAN, M. H. **The measurement of water evaporation from limited areas of a normal body surface.** *J. Animal Sci.*, 1954, **13**, 405-416. [Bur. Dairy Indust., Agric. Res. Centre, Beltsville, Md.]

An apparatus is described and illustrated for measuring the rate of water evaporation from selected rectangular areas, 10 sq. cm., of skin without greatly altering the humidity of the air to which they are exposed. A capsule is attached to the skin and the absorber tubes contain a saturated solution of a salt of the desired vapour pressure. In the closed circuit is a diaphragm pump and a rotometer to measure the rate of air flow. When measurements are not being made a similar maintenance equipment which can serve 3 or 4 capsules simultaneously is used. Evaporation from the skin is measured by gain in weight of the absorber.

Preliminary experiments with one cow showed that at 100° F. ambient temperature and 29 mm. Hg vapour pressure the rate of evaporation varied for different parts of the body, being lowest on loin and neck and highest on paunch and withers. It increased at all points with rise in temperature, the increase being relatively greater for those areas with lower values at the lower temperature. No significant difference was found between Jersey and Jersey Sindhi cows for areas on the forechest and paunch under the same conditions. At 105° F. and 34 mm. Hg vapour pressure rates of evaporation for these areas reached 660 g. per sq. m. per hr. With the same technique under the same hot condition rabbits showed little or no evaporation.—W. Godden.

SCHÜRCH, A. Die Verdauungskoeffizienten: Bestimmung, Berechnung und Signifikanz. [Coefficients of digestibility: estimation, computation and significance.] *Kraftfutter*, 1953, No. 2. English summary.

The importance of an accurate knowledge of the digestibility coefficients of the nutrients in a feed or ration for its proper evaluation is stressed. Methods of estimating or computing such coefficients are briefly reviewed. A formula is given for calculating digestibility coefficients by difference:

$$Y = 100 \frac{(T \pm G) - (X \pm G)}{y} + (X \pm G),$$

where X is the digestibility of the basal feed, Y that of the supplement, T that of the basal feed plus supplement, y the percentage of the supplement in the total ration and G the standard deviation inherent in such experiments. The use of radio-active isotopes in the estimation of true digestibility values is briefly discussed.

LANCASTER, R. J. and BARTRUM, M. P. Measurement of feed intake by grazing cattle and sheep. 4. A source of error in the chromogen technique of estimating the digestibility of fodders. *N.Z. J. Sci. Technol.*[A], 1954, 35, 489-496. [Animal Res. Div., Dept. Agric., Ruakura Animal Res. Stat., Hamilton.]

For previous parts see Absts. 133, Vol. 21; 2679, Vol. 23; 2452, Vol. 24.

The stability of chromogen solutions prepared by extracting fresh faeces with 85 per cent. acetone in the dark was examined by measurement of the optical density at 406 $\text{m}\mu$. The optical density increased rapidly on exposure to light, the rate of increase being a function of light intensity and time. It is recommended that readings be made within 6 hr. of the preparation of the extract, since the optical density of extracts kept in the dark remains constant for that length of time; it increases by 20 to 30 per cent. over the next 10 days. Pasture chromogen solutions kept in the dark at room temperature did not change in optical density over long periods (1 year).

DAVIDSON, J. The chromogen method for determining the digestibility of dried grass by sheep. *J. Sci. Food Agric.*, 1954, 5, 209-212. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Four sheep were used in an experiment to compare the digestibility of dried grass when estimated by the standard total collection method and by the ratio method that uses as index the plant chromatogens extracted from the food and faeces by 85 per cent. acetone and estimated from their light absorption at wavelength 406 $\text{m}\mu$.

Digestibility values obtained by the chromogen method were low when extracts were read at 406 $\text{m}\mu$. and agreed more nearly with the total collection method when read at 416 $\text{m}\mu$. It was concluded that for general use the chromogen method was applicable only when comparative trials had shown general agreement with the other method.

The losses of pigment in their passage through the alimentary tract were measured and shown to vary from 18 per cent. for the carotenoids to 62 per cent. for the total fat-soluble tetrapyrroles and 87 per cent. for chlorophylls. These values varied from sheep to sheep.—D. M. Walker.

TAYLOR, W. B. and ARMSTRONG, P. J. The efficiency of some experimental designs used in dairy husbandry experiments. *J. Agric. Sci.*, 1953, 43, 407-412. [Appl. Mathematics Lab., D.S.I.R., New Zealand.]

N.A. and R., October 1954

A study is made of the relative efficiencies in dairy husbandry experiments of different experimental designs of the reversal, Latin square, and incomplete Latin square types. From a mixed cow herd, representative of good New Zealand grade herds, 48 complete lactation records for uniformity trials of these types were obtained. Data from the 40th to the 200th day after calving were used, split up into 3- or 5-week periods, separated by intervals of a week, which would be necessary in practice to allow for residual effects. Measurements analysed were milk yield, fat yield, solids-not-fat, and fat percentage.

The types of experiment considered are those in which 2, 3 or 4 treatments have to be compared, and in which data are collected in 3 or 4 consecutive periods. The relative efficiencies of the different designs are shown as the ratios of the variances of treatment comparisons taken two at a time. It was found (1) that experiments conducted during the earlier part of the lactation are more efficient than those during the later part, (2) that early experiments with 3-week periods are more efficient than experiments with 5-week periods, (3) that an extension from 3 to 4 periods reduces error in the case of 3-week periods but not of 5-week periods, since four 5-week periods carry the experiments into the more variable part of the lactation, and (4) that little benefit is obtained by grouping the animals according to yields recorded during the first 40 days of lactation.

Results of comparisons between reversal and Latin square experiments are different in different cases, and possible reasons for this are discussed.

Results are not quoted for comparisons between the designs above and ordinary group trials, but it is stated that these confirm the acknowledged superiority of the more elaborate designs.

IVINS, J. D. **The measurement of pasture output on the dairy farm.** *J. Brit. Grassland Soc.*, 1953, **8**, 337-344. [Sch. Agric., Univ. Nottingham.]

A study was made of the method of gauging pasture output by calculation of the starch equivalent utilised by grazing dairy herds. This method of measuring pasture output on a farm scale is the one on which most emphasis is placed in Great Britain at the present time. Its main disadvantage is that it is a measurement of the amount utilised by the grazing animals rather than of the amount available, and so different results would be obtained for the same pasture grazed by different herds. The object of the study was to discover which characteristics of the animals were important in this respect. From the examination of detailed records from 382 dairy cows it was found that the most important variant was time of calving in relation to time of

peak pasture output. Tentative correction factors are put forward to enable results to be adjusted to the values that would have been obtained from a grazing herd of standard composition with respect to times of calving. It is suggested that these corrected values of utilised starch equivalent would provide better measures of pasture output than do the crude values.—I. McDonald.

BENNETT, E. and ARCHIBALD, J. G. **A simple test of quality in hay.** *J. Dairy Sci.*, 1954, **37**, 552-555. [Dept. Chem., Massachusetts Agric. Exp. Stat., Amherst.]

Three g. dry hay ground to pass a 0.5 mm. sieve are suspended in 200 ml. water containing 4 or 5 drops of acetic acid. The mixture is agitated for 5 min. in a blender, made up to 500 ml. and centrifuged at 1500 r.p.m. for 5 min. The supernatant liquid is poured through a thin layer of glass wool and the optical density of the filtrate is measured in a spectrophotometer at 675 m μ . with a PC-5 Corning filter, and distilled water as reference liquid. Tests with 10 samples of hay and 6 of oven-dried fresh grasses or legumes showed highly significant correlations between optical density and crude protein, $r = +0.86$; optical density and crude fibre, $r = -0.82$; and optical density and protein:fibre ratio, $r = -0.81$. A preliminary test in 2 seasons with 3 cows in each showed a decline in milk production when the cows were transferred from "good" to "poor" hay and vice versa.—W. Godden.

There was a multiple correlation coefficient of 0.912 between the sp. gr. of the lean of hams and the percentages of moisture, protein and ether extract. The correlation might have been even higher had it not been for errors in the sampling of the meat before chemical analysis. A subsidiary trial showed that 8 per cent. of the total variation in moisture content between hams and 11.3 per cent. of the variation in ether extract were due to the errors in sampling.

There was a high correlation between the sp. gr. of hams and the half carcasses from which they came, which suggested that the proportions of the tissues in the ham are indicative of the proportions of these tissues in the entire carcass.

Correlations between the sp. gr. of the hams and the percentages of the various components of the ham were calculated; percentage lean and percentage fat were much more closely associated

with the sp. gr. than was the percentage bone. Correlations between the sp. gr. of the half carcasses and the percentage bone were positive and significant, but were very much reduced when percentages of lean cuts were held constant by partial correlation.

Simple intra-breed correlations were calculated between 8 measures of carcass leanness and sp. gr. and also between the 8 measures and average backfat thickness. For one set of data sp. gr. was significantly more highly correlated with the 8 measures than was average backfat thickness, but although the same trend was evident in a second set of data the differences between correlation coefficients was not statistically significant.

A discussion of some points in the use of the sp. gr. technique is also included.—I. A. M. Lucas.

SCHORMÜLLER, J. and KREMPIEN, J. Über den Einfluss der Glucose auf den Threonin-, Serin- und Stickstoffgehalt des Caseins beim Erhitzen. [Effect of glucose on the threonine, serine and nitrogen content of heated casein.] *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1954, **98**, 1-18. [Inst. Lebensmittelchem., Tech. Univ., Berlin-Charlottenburg.]

The literature is reviewed. Threonine and serine were estimated by periodate oxidation (Abst. 3812, Vol. 16). The casein used contained N 15.15, water 8.27, serine 5.95 and threonine 4.15 per cent. Samples of casein alone or with equal parts of glucose were heated in air to temperatures between 100° and 200° C. The results are shown graphically.

Heated to 200° C., the mixture lost twice as much water as casein alone, and browning began as low as 120° C. Casein alone lost little N; threonine and serine began to fall rapidly at about 170° C. and at 200° C. only about 20 per cent. remained. The mixture began to lose N, threonine and serine at about 120° C. but the end results for threonine and serine were much the same. Prolonged heating of casein at 160° C. did not affect threonine, but serine fell during the first 30 min., thereafter more slowly; at 200° C. both fell rapidly at first and then more slowly [text, p. 9; not in agreement with fig. 4]. In presence of glucose, N, threonine and serine all fell rapidly at first; at 200° C. the reaction was almost complete in 30 min., at 160° C. in 90 min.

Heating in nitrogen instead of air reduced the losses. Heating with olive oil to simulate the use of fat in cooking speeded up the loss of threonine and serine from casein alone, but did not greatly affect the mixture. Unlike egg protein (Schormüller and Walter, *Ztschr. anal. Chem.*, 1951, **134**, 337) casein refluxed with water or 5 per cent. glucose did not lose N, threonine or serine, though with glucose there was browning. Storage with or without glucose for 2 months at 37° C. was also without effect.

Ultraviolet absorption curves of hydrolysates of treated samples showed increased absorption and a progressive flattening at higher temperatures of the minimum and maximum characteristic of casein; with glucose the effect set in at a lower temperature. It is considered that the position and shape of the absorption curve can be taken as a measure of the damage.—W. M. Deans.

ROSE, D. and TESSIER, H. Effect of freezing rate on stability of frozen milk. *Canad. J. Technol.*,

Vol. 24, No. 4

1954, **32**, 85-90. [Div. Appl. Biol., Nat. Res. Labs., Ottawa.]

Samples of milk, whole or concentrated, were stored at -12° C. after being frozen at different temperatures. The least stable were those treated at the very low temperature -196° C.; those frozen at -7° C. had the longest storage life. Freezing rate was varied by initiating ice formation at -12° C., continuing at -3° C. for 24 or 48 hr. and completing it at -12° C. Both treatments increased storage life. When the final storage temperature was -18° C. results were not so consistent. Slow freezing, it is concluded, will be advantageous in marketing conditions where the storage period is short and where temperatures, e.g., in display cabinets, are about -12° C. (+10° F.).—D. Harvey.

POOL, M. F., MECCHI, E. P., LINEWEAVER, H. and KLOSE, A. A. The effect of scalding temperature on the processing and initial appearance of turkeys.

KLOSE, A. A. and POOL, M. F. Effect of scalding temperature on quality of stored frozen turkeys. *Poultry Sci.*, 1954, **33**, 274-279; 280-289. [W. Reg. Res. Lab., Albany, Calif.]

Groups of 10 carcasses from 6-month-old Broad Breasted Bronze turkeys were scalded at temperatures of 122° to 140° F. for 30 to 120 sec. and thereafter processed by commercial dressing machinery. Half the group was chilled in slush ice and the other in air at 39° F. The toms were New York dressed and the hens eviscerated; the carcasses were then frozen at -30° F. for at least 48 hr. and held at -5° F.

Raising the temperature of scalding was more favourable to feather removal than increasing the time beyond 60 sec., but skin was lost as a result. Air chilling gave very uniform weight loss within a group, smaller with lower scalding temperature. For the second part of the study the New York dressed toms were frozen in wooden boxes lined with waxed paper and 2 groups had an additional layer of water-saturated paper pulp to reduce moisture loss and freezer burn. The eviscerated hens were packed in twist-sealed, heat-shrunk plastic bags stored in wooden boxes lined with paper.

The gross weight loss before thawing for the New York dressed toms was 1 per cent. per box; individual results for the thawed carcasses showed that the higher the scalding temperature, the greater the loss, irrespective of the method of chilling. Ice-chilled birds lost over twice as much as air-chilled. The paper pulp halved the moisture loss. Eviscerated hens stored in plastic bags showed a negligible weight loss over 12 months at -5° F., and little change in appearance, whereas New York dressed toms scalded at the higher temperatures were unacceptable in appearance after 3 months' storage.

Fat rancidity was slight in all the stored carcasses, most being observed in the exposed visceral fat of eviscerated hens.

All birds were acceptable to the taste panel in respect of toughness of roasted breast or leg muscle and skin. Variations in scalding and chilling had no effect on muscle toughness; scalding at 140° F. toughened the skin, but this could be overcome by the cooking procedure. The findings on toughness were confirmed by shear force measurements by the Warner Bratzler apparatus.—M. J. Head.

4224

PIPPEN, E. L., CAMPBELL, A. A. and STREETER, I. V. Flavor studies. Origin of chicken flavor. *J. Agric. Food Chem.*, 1954, **2**, 364-367. [W. Utilization Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Albany 6, Calif.]

Studies were made of the contributions to flavour by the gross parts of chicken carcasses. The standard conditions of preparation of broth, nominally by cooking for 3 hr., are described. The results were those assigned by a taste panel of 8 judges.

The layer of fat which covered it contributed little to the flavour or odour of the broth. When meat, bones and skin were cooked separately and compared with broth made from these in natural proportions most of the flavour was found in the meat, rather less in the composite material and much less in the bones or skin. Results for odour were similar. No significant difference was found to exist between light and dark meat. Cold water extraction removed important precursors of the flavour of the meat but results for odour were not so definite.—D. Harvey.

TARE, H. L. A., BOYD, J. W. and BISSETT, H. M. Experimental preservation of fish and beef with antibiotics. *J. Agric. Food Chem.*, 1954, **2**, 372-375. [Pacific Fish. Exp. Stat., Vancouver 2, B.C.]

When ice containing 1, 2 or 4 p.p.m. chlorotetracycline (aureomycin hydrochloride) or 2 p.p.m. chlorotetracycline plus 200 p.p.m. KH_2PO_4 , uniformly distributed, was used to preserve eviscerated lingcod landed within 24 hr. of capture the bacterial counts after a fortnight were only about one-seventh of those with ordinary ice, and on organoleptic examination fish iced in the ordinary way showed obvious staleness 4 or 5 days earlier than the experimental fish. Similar good results were obtained when red spring salmon was stored on the boat for 6 days at -1° C. in sea water containing 2 μg . chlorotetracycline per ml. Immersion of Coho salmon for 1 min. in sea water containing chlorotetracycline before icing with ordinary ice was not effective, but immersion of lingcod for 1 min. in a 3 per cent. salt solution plus 50 or 100 μg . chlorotetracycline per ml. before ordinary icing gave bacterial counts after 10 days negligible compared to those with brine alone.

Added chlorotetracycline was found to be fairly stable in minced fish or beef stored for 2 days at 4° C. but was rapidly destroyed by heating. The A.O.A.C. pad-plate microbiological method of estimating chlorotetracycline was not satisfactory for estimations on fish preserved with ice containing chlorotetracycline.—W. M. Deans.

NIKKILÄ, O. E. and LINKO, R. R. **Denaturation of myosin during defrosting of frozen fish.** *Food Res.*, 1954, **19**, 200-205. [Central Lab., Tukkukauppojen Oy, Turku, Finland.]

Changes in frozen fish, resulting in a drier muscle with a coarser texture, are thought to be due to denaturation of the proteins. In this work loss of brine-extractable myosin was used as a measure of denaturation. Myosin N was estimated in brine extracts of fillets of Baltic herring (*Clupea harengus* var. *membranus*) either fresh or after freezing in an air blast at -35° , storing at -20° and defrosting in air at 18° C. The results are shown graphically.

After about 17 hours' defrosting, brine-extractable myosin N declined gradually in fish frozen immediately after *rigor mortis*. In fish frozen during *rigor mortis* the fall began earlier and was much more rapid. Brine-extractable myosin N was greater during defrosting and subsequent storage in fish which had been stored for 34 or 58 hr. before freezing than in those frozen fresh. Freezing and defrosting for a second time reduced brine-extractable myosin N to very low amounts. These results are in conflict with the views of other workers that immediate freezing, followed by thawing, filleting and refreezing, has no adverse effect on quality.—W. M. Deans.

4227

SIEBURTH, J. F., WAHL, T. and McLAREN, B. A. **Effect of added softeners on moisture content of bread.** *J. Amer. Dietetic Assoc.*, 1954, **30**, 355-357. [Dept. Home Econ., State Coll. Washington, Pullman.]

Breads made from white or whole wheat flour with or without 0.5 per cent. polyoxyethylene stearate or 1.5 to 3.5 per cent. potato starch were stored for 3 days at 30° C. and relative humidity 85 per cent. Whole wheat bread lost moisture more slowly than did white bread. The stearate reduced the rate of water loss from the white but not from the whole wheat bread. Potato starch had no appreciable effect.—F. C. Aitken.

4228

SINGH, R., RAFIQUE, M. and BAINS, G. S. **Investigations on the preparation and use of sweet potato and groundnut cake flours in conjunction with wheat for leavened bread (*dabal roti*) and chapatis.** *Indian J. Agric. Sci.*, 1953, **23**, 139-146. [Milling and Baking Lab., Punjab Agric. Coll., Lyallpur.]

The value of sweet potato flour prepared from scalded or unscalded tubers was studied. Scalding had the effect of inactivating undesirable enzymes which caused discolouration, and partially gelatinising the starch, which improved the quality of the

dough for chapatis. For such use up to 30 per cent. of the wheat could be replaced. When groundnut cake was the replacement not more than 5 per cent. could be used.

When leavened bread was to be prepared the limit of replacement by each flour was 5 per cent. D. Harvey.

MILNER, M. and THOMPSON, J. B. **Grain storage. Physical and chemical consequences of advanced spontaneous heating in stored soybeans.** *J. Agric. Food Chem.*, 1954, **2**, 303-309. [Kansas State Coll., Manhattan.]

The physical appearance of samples of soya beans from 2 typical instances of spontaneous heating in storage bins is described, and the results of chemical analyses are tabulated and contrasted with those for soya beans heated directly. The findings are discussed in conjunction with the literature and previous work by one of the authors (Title 3023, Vol. 15; Absts. 1422, 3917, Vol. 16). It was concluded that actual combustion did not occur but that the main chemical change in the second stage of spontaneous heating was the exothermic browning (Maillard) reaction, for which soya beans supply ample proteins and sugars, and also trace elements, such as Cu, which possibly catalyse the reaction. It is suggested that this reaction may play a part in the heating of other stored crops also.

A theory of the process of heating in soya beans stored in bulk is put forward, with practical recommendations.—W. M. Deans.

4230

ROBERTS, R. L., POTTER, A. L., KESTER, E. B. and KENEASTER, K. K. **Effect of processing conditions on the expanded volume, colour, and soluble starch of parboiled rice.** *Cereal Chem.*, 1954, **31**, 121-129. [W. Reg. Res. Lab., Albany, Calif.]

In the parboiling of rice, colour development increased rapidly as steaming temperature rose to 212° F. There was an increase also in soluble starch content and in the degree of expansion of the dry milled rice when heated in air at 482° F. It is suggested that estimation of soluble starch and degree of expansion might form a basis for measuring the degree of parboiling.

JARL, F. and HELLBERG, A. Ensileringsförsök med sura natriumsalter av fosforsyra och svavelsyra. [Ensiling experiment with acid sodium salts of phosphoric and sulphuric acid.] Tabellbilaga till Meddelande Nr 54. [Tabular appendix to Medd. No. 54.] *Kgl. Lantbrukshögsk. Statens Husdjursförsök Medd.* No. 54, 1954, pp. 38+16. English summary.

Preliminary trials were made with 6 salts, of which NaH_2PO_4 was later omitted on account of its high price and high P content, double superphosphate because of its high F content and NaHSO_4 because of its high S content and laxative effect. There remained NaH_2PO_4 with 1, 2 or 3 molecules of NaHSO_4 . Silage was made in small and big concrete silos and in pits. The small silos had drains from which the effluent could be collected. Each series had control samples put down with A.I.V. solution and without addition. The crops were grass, clover and alfalfa and a few samples of yellow sweet lupin. The results are presented in detail.

The preserving action of the salt increased with its content of sodium acid sulphate, but since the suitability of this in a feed was in doubt, most work was done with the salt with least sulphate, to which the following summary refers. Increasing the amount of salt from 1 to 2 per cent. of the fresh weight of crop made little difference to losses from the silage. The P content of the silage was increased by 2 to 2.5 g. per kg. when 1.5 per cent. of salt was used.

It made little difference whether the salt was used dry or in solution. Under good conditions 1 per cent. gave good silage: under bad conditions 2 per cent. gave slightly better quality. Compared with A.I.V. silage, in general pH, ammonia, lactic acid and acetic acid were all higher in phosphate silage and losses of nutrients were sometimes slightly greater, but there was no more butyric acid. Yellow sweet lupin gave consistently good results.

An appendix, printed separately, gives supplementary tabular data.—I. Leitch.

2. CHEMICAL COMPOSITION OF FOODSTUFFS

(Except Vitamins, for which see Section 3.)

ENERGY VALUE, PROXIMATE PRINCIPLES AND INORGANIC CONSTITUENTS

GENERAL

- 4244
AHMAD, K., KARIM, M. A. and DE, H. N. Choline contents of some common Bengal foodstuffs. *Indian J. Med. Res.*, 1953, 41, 441-445. [Div. Biochem. Nutrit., Univ. Dacca, E. Pakistan.]
Choline was estimated in 27 species of fish and 33 vegetables by the ammonium reineckate method of Luecke and Pearson (Abst. 2911, Vol. 14). For the fish, values ranged from 15.6 to 37.7 mg. choline chloride per g. dry tissue. Values ranging from 0.88 to 25.10 mg. per g. were found in vegetables.—P. C. Jowsey.
- 4245
PEREIRA E SANTOS, P. O. Os ácidos gordos essenciais nas gorduras alimentares portuguesas. [Essential fatty acids in food fats in Portugal.] *Agronom. lusitana*, 1953, 15, 193-242. [Estação Agron. Nac.] English summary.
Linoleic, linolenic and arachidonic acids were estimated spectrophotometrically in olive, groundnut, sesame, coconut and palm oils, butter, margarine and lard. Linoleic acid was found in all, linolenic in all except coconut oil, but arachidonic acid in butter and lard only. The average daily intake per head of essential fatty acids in Portugal was 3614.2 mg., equivalent to 1.47 per cent. of the daily energy intake.
It is pointed out that in any attempt to raise the average daily energy intake, attention should be paid to the ratio of essential fatty acids to energy so that intake of energy in the form of essential fatty acids should not fall below 1 per cent. of the total, which is the minimum recommended by the National Research Council (Washington).—P. C. Jowsey.

ROBERTS, H. R., PETTINATI, J. D. and BUCEK, W. A comparative study of human, cow, sow, and rat milk using paper chromatography. *J. Dairy Sci.*, 1954, 37, 538-545. [National Dairy Research Laboratories, Inc., Oakdale, Long Island, N.Y.]

The chromatograms of human, cow, rat and sow milk, obtained after removal of proteins and salts, showed some marked differences. All contained lactose, but in addition human milk contained 11 other unidentified spots, compared with 10, 6 and 8, for cow, rat and sow milk, respectively. Trace quantities of glucose and galactose were found in cow and sow milk, and human milk contained glucose, but rat milk contained neither galactose nor glucose. There are strong indications that the additional spots in these chromato-

grams represent substances of a carbohydrate nature. The samples of human milk were taken at 3, 7, 23 and 44 days *post partum*: those of cow's milk at 3, 27, 51, 75 and 147 hours *post partum*; those of rat's milk at 1, 3, 6 and 13 days *post partum*. The lactating day for the sow's milk was not known.—M. B. Richards.

4254

DE MUNTER, P. Relations entre protéines et matières grasses du lait. Etude statistique. [Relations between protein and fat in milk. A statistical study.] *Bull. Inst. agronom. Gembloux*, 1953, 21, No. 1/2, 29-36.

A study is made of sets of data for the protein and fat contents of milk published by Bonnier, Antoine and De Vuyst. Finding, with Bonnier's data, that a linear regression of protein content on fat content did not give a satisfactory fit, the author went on to fit a relationship of exponential type, which did fit the data. A similar procedure applied to Antoine's data also gave improved fit, but it was not suited to the third set of results. The theoretical difficulties are discussed that arise in the analysis of sets of data, such as the second and third sets considered, if their collection is not carefully designed from a statistical point of view.

SRINIVASAN, P. R. and RAMANATHAN, M. K. Protein and sulphur amino acids in breast-milk of poor class Indian women in the Nilgiris. *Indian J. Med. Res.*, 1954, 42, 51-54. [Nutrit. Res. Labs., Indian Counc. Med. Res., Coonoor, S. India.]

Milk samples were collected from 25 apparently healthy Indian mothers and from 6 who had a child suffering from kwashiorkor.

The average protein content of the milk of both groups, and its methionine content, were comparable with those given for white American and British women. The cysteine content was slightly lower. There was no difference between the 2 groups of Indian women. [No data are given of the total yield of milk, or of the ages of the children with kwashiorkor and their diet apart from breast milk.]—F. E. Hytten.

4256

MORTON, R. K. The lipoprotein particles in cow's milk. *Biochem. J.*, 1954, 57, 231-237. [Dept. Biochem., Univ. Cambridge.]

In an attempt further to characterise the lipoprotein particles of milk (see Abst. 1624, Vol. 24), 2 types of particles were isolated, one from buttermilk, the other from separated milk, by procedures which are described. Comparative analyses of chemical and enzymic composition were made and electron micrographs were prepared.

N.A. and R., October 1954

The particles from buttermilk were opaque and orange-pink in colour. By the presence in them of total lipid, nucleic acid P, alkaline phosphatase, xanthane oxidase and diaphorase they resembled the microsomes isolated from mammary tissue, and the term "milk microsomes" is proposed for them. In the electron micrograph the particles were in indefinite clumps. They possessed no succinic dehydrogenase or cytochrome oxidase activity.

The particles from separated milk were clear and translucent; they contained much less lipid than the microsomes, and had little enzyme activity. In the electron micrograph these casein particles showed a regular and distinctive clumping.

D. Harvey.

SMITH, L. M. and JACK, E. L. **The unsaturated fatty acids of milk fat. 1. Methyl ester fractionation and isolation of monoethenoid constituents. 2. Conjugated and nonconjugated constituents.**

SMITH, L. M., FREEMAN, N. K. and JACK, E. L. **3. Geometrical isomerism.** *J. Dairy Sci.*, 1954, **37**, 380-389; 390-398; 399-406. [Dept. Dairy Indust., Univ. California, Davis.]

1. The concentrations of unsaturated fatty acids, weight per cent. as calculated from methyl ester distillation data, were: decenoic 0.19, dodecenoic 0.27, tetradecenoic 1.52, hexadecenoic 3.12, octadecenoic 33.14, linoleic plus other unsaturated acids 4.03. The methyl esters were prepared by a procedure with pentane as solvent, and for low temperature crystallisation for 24 hr. at -21°C . pentane was better than the 2 other solvents, absolute ether and absolute methanol, which were tested. For separating saturated and unsaturated methyl esters such crystallisation was more efficient than extractive crystallisation with urea.

2. The amounts of polyunsaturated fatty acids in Californian milk fats agreed with data published elsewhere. Methyl esters of polyethenoid fatty acids were concentrated by removal of saturated and monoethenoid components as described. Milk fat was shown to contain small amounts of conjugated and nonconjugated dienoic, trienoic and tetraenoic fatty acids with carbon chain lengths 18 or longer.

3. Infra-red absorption spectra were recorded for C_{18} , C_{16} , C_{14} , C_{12} , and C_{10} monoethenoid methyl ester fractions of milk fat and for three C_{18-20} fractions containing different distributions of polyethenoid constituents; the spectral similarities and differences are discussed.—D. Harvey.

SVENDSEN, A. B. and JERMSTAD, A. **Amino acids in gammelost. A paper chromatographic investigation.** *Netherlands Melk Zuiveltijdschr.*, 1954, **8**, 29-33. [Pharm. Inst., Univ. Oslo.] Dutch summary.

Gammelost is a Norwegian cheese made from acidified, pasteurised, skimmed milk by the Hardanger or the Sogn method. Both types were examined. The ripe cheese has a higher protein N and lower free amino-acid N and ammonia N contents in the inner than in the outer layers. The free amino-acids were extracted by aqueous alcohol and after evaporation of the alcohol were separated and identified by 2-dimensional paper chromatography. Amino-acids normally present were: glutamic acid, aspartic acid, serine, glycine, threonine, glutamine, alanine, proline, γ -aminobutyric acid, valine, phenylalanine, leucine and isoleucine. Lysine and ornithine were frequently present and in some samples tyrosine and possibly α -aminobutyric acid.—W. Godden.

4263

SCHORMÜLLER, J., LIESE, H. and WINTER, H. Beiträge zur Biochemie der Käsereifung. 2. Die Stickstoffbilanz im Verlauf der Reifung von Sauermilch-Magerkäse verschiedener Herstellungsart. [Biochemistry of cheese ripening. 2. Nitrogen balance during the ripening of sour skimmed milk cheese made in different ways.] 3. Das Verhalten des Arginins im Verlauf der Reifung. [3. Behaviour of arginine in the course of ripening.] *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1954, **98**, 258-274; 347-358. [Inst. Lebensmittelchem., Tech. Univ., Berlin, Charlottenburg.]

2. Very detailed studies were made of changes in the nitrogen fractions during the ripening of Harz cheese (sour skimmed milk cheese) made in the usual way with 1.8 kg. salt, 0.40 kg. NaHCO_3 and 0.10 kg. CaCO_3 per 50 kg. curd, or with the same proportion of salt, 0.75 kg. NaHCO_3 and 0.38 kg. CaCO_3 to accelerate ripening, or with nothing added. The methods are briefly described and the results are presented in graphs and in tables giving true protein N, residual N, soluble and insoluble protein N and soluble N.P.N. as percentages of crude protein N, and amino-acid N, peptide N, ammonia N and urea N as percentages of residual N and of crude protein N.

During normal ripening (about a fortnight), soluble protein and residual N increase. Amino-acids are the principal constituent of residual N. As a percentage of crude protein N, amino-acids, ammonia and urea increase during ripening; peptides also at first, but in over-ripe cheese these decline.

In accelerated ripening soluble protein decreases instead of increasing. The proportion of free amino-acids is smaller and that of peptides greater and as a result the flavour of the cheese is insipid. It is concluded that hastening ripening has no advantage from the point of view of nutritive value or quality.

The widely different changes in unsalted curd are also described. The product is unpalatable and useless.

3. The material was as above; arginine was estimated by the method of Kraut *et al.* (*Hoppe-Seyler's Ztschr.*, 1950, **286**, 248) and the results are presented in tables.

During normal ripening only about 8 per cent. of the arginine was lost, less during accelerated ripening, and the cheese contained no free arginine or only a trace. It was concluded that neither normal nor accelerated ripening affects the biological value of the protein so far as arginine is concerned, and that arginine has nothing to do with the flavour of this cheese.

The dry matter of egg white and egg yolk contain, respectively, 1.974 and 1.929 per cent. total S, of which 0.003 and 0.007 is sulphate S. Of the protein-bound S in egg white 71.2 per cent. is present as methionine and 28.2 per cent. is cystine-cysteine. For egg yolk the figures are 92 and 8 per cent., respectively.—W. Godden.

SCHWEIGERT, B. S., BENNETT, B. A. and GUTHNECK, B. T. Amino acid composition of organ meats. *Food Res.*, 1954, **19**, 219-223. [Div. Biochem. Nutrit., American Meat Inst. Found., Chicago, Ill.]

Ten amino-acids were estimated in composite samples from 2 sources of liver, kidney, heart, brain, pancreas, lung and spleen from beef, pork and lamb carcasses. Liver had more leucine, valine and methionine than other organs; lung and spleen tended to have less of several acids than the other organs. The tryptophan content of pork pancreas was high compared with that of the other organs of each species.—D. Harvey.

LOFGREEN, G. P. and GARRETT, W. N. Creatinine excretion and specific gravity as related to the

N.A. and R., Octobe 1954

composition of the 9, 10, 11th rib out of Hereford steers. *J. Animal Sci.*, 1954, **13**, 496-500. [Dept. Animal Husb., Univ. California, Davis.]

Nine long-yearling steers were full-fed on a ration containing oat hay 40, ground barley 43, dried beet pulp 12, cottonseed meal 4, oyster shell flour 0.5 and salt 0.5 per cent. A similar group of 9 received the same ration except that the cottonseed meal was replaced by 3.8 per cent. dextrose and 0.2 per cent. KH_2PO_4 . Animals from each group were killed at intervals from 94 to 154 days from the start. Before slaughter each steer was fed on oat hay alone for 12 days and creatinine was estimated in the total urine during the last 5 days. The ninth-tenth-eleventh-rib cut was taken from the right side of each carcass by the method of Hankins and Howe (Abst. 1609, Vol. 17). The sp. gr. of the cut was measured and the lean, fat and bone were separated manually and their sp. gr. was measured.

Creatinine excretion per unit bodyweight and the percentage of separable lean in the soft tissue of the rib cut showed a significant correlation ($r = +0.67$). The separable fat (F) of the rib sample could be predicted accurately from the sp. gr. (G_w) of the whole rib cut by the equation

$$F = \frac{1.155 - G_w}{0.261}$$

W. Godden.

HANSEN, R. P. and McINNIS, A. G. **Volatile acids of ox perinephric fat.** *Nature*, 1954, **173**, 1093. [Fats Res. Lab., D.S.I.R., Sydney St. W., Wellington, N.Z.]

A sample of beef suet from the perinephric fat was steam-rendered and the glycerides were hydrogenated with an Ni catalyst. The products were saponified with KOH, the soaps converted to acids and the fatty acids steam-distilled. The steam distillate was neutralised with KOH and the individual K soaps were isolated by the gas-liquid partition chromatographic technique of James and Martin (Abst. 77, Vol. 22). All the acids from C_2 to C_{10} inclusive were identified and evidence was obtained of the presence of another unidentified acid, possibly an isomer of decanoic acid.—W. Godden.
